## CLIMATE DIAGNOSTICS BULLETIN

### CLIMATE PREDICTION CENTER Attn: Climate Diagnostics Bulletin W/NP52, Room 605, WWBG Camp Springs, MD 20746-4304

**Chief Editor:** Gerald D. Bell

**Editors:** Wei Shi, Michelle L'Heureux, and Michael Halpert

**Bulletin Production:** Wei Shi

**External Collaborators:**

Center for Ocean-Atmospheric Prediction Studies (COAPS)

Cooperative Institute for Research in the Atmosphere (CIRA)

Earth & Space Research

International Research Institute for Climate and Society (IRI)

Joint Institute for the Study of the Atmosphere and Ocean (JISAO)

Lamont-Doherty Earth Observatory (LDEO)

NOAA-CIRES, Climate Diagnostics Center

NOAA-AOML, Atlantic Oceanographic and Meteorological Laboratory

NOAA-NESDIS-STAR, Center for Satellite Applications and Research

NOAA-NDBC, National Data Buoy Center

Scripps Institution of Oceanography

**Software:** Most of the bulletin figures generated at CPC are created using the Grid Analysis and Display System (GrADS).

**- Climate Diagnostics Bulletin available on the World Wide Web**

The CDB is available on the World Wide Web. The address of the online version of the CDB is:

**<http://www.cpc.ncep.noaa.gov/products/CDB>**

If you have any problems accessing the bulletin, contact Dr. Wei Shi by E-mail:

## Tropical Highlights - November 2011

La Niña conditions continued during November 2011 as sea surface temperature anomalies were well below  $-0.5^{\circ}\text{C}$  across the eastern and central equatorial Pacific Ocean (**Fig. T18, Table T2**). The latest monthly Niño indices were  $-1.1^{\circ}\text{C}$  for the Niño 3.4 region and  $-0.8^{\circ}\text{C}$  for the Niño 1+2 region (**Table T2, Fig. T5**). Consistent with these conditions, the oceanic thermocline (measured by the depth of the  $20^{\circ}\text{C}$  isotherm) remained shallower than average in the east-central equatorial Pacific (**Figs. T15, T16**), where corresponding sub-surface temperatures were  $1-5^{\circ}\text{C}$  below average (**Fig. T17**).

Also in November, the equatorial low-level easterly trade winds and upper-level westerly winds were stronger than average over the western and central equatorial Pacific (**Table T1, Figs. T20, T21**). Convection remained suppressed near the Date Line and enhanced across Indonesia and northern Australia (**Figs. T25, E3**). Collectively, these oceanic and atmospheric anomalies reflect a continuation of La Niña conditions.

For the latest status of the ENSO cycle see the ENSO Diagnostic Discussion at:

TABLE T1 - Atmospheric index values for the most recent 12 months. Indices are standardized by the mean annual standard deviation, except for the Tahiti and Darwin SLP anomalies which are in units of hPa. Positive (negative) values of 200-hPa zonal wind index imply westerly (easterly) anomalies. Positive (negative) values of 850-hPa zonal wind indices imply easterly (westerly) anomalies. Anomalies are departures from the 1981-2010 base period means.

TABLE T2. Mean and anomalous sea surface temperature (°C) for the most recent 12 months. Anomalies are departures from the 1981–2010 adjusted OI climatology (Smith and Reynolds 1998, *J. Climate*, **11**, 3320–3323).

FIGURE T1. Five-month running mean of the Southern Oscillation Index (SOI) (top), sea-level pressure anomaly (hPa) at Darwin and Tahiti (middle), and outgoing longwave radiation anomaly (OLR) averaged over the area 5N-5S, 160E-160W (bottom). Anomalies in the top and middle panels are departures from the 1981-2010 base period means and are normalized by the mean annual standard deviation. Anomalies in the bottom panel are departures from the 1981-2010 base period means. Individual monthly values are indicated by “x”s in the top and bottom panels. The x-axis labels are centered on July.

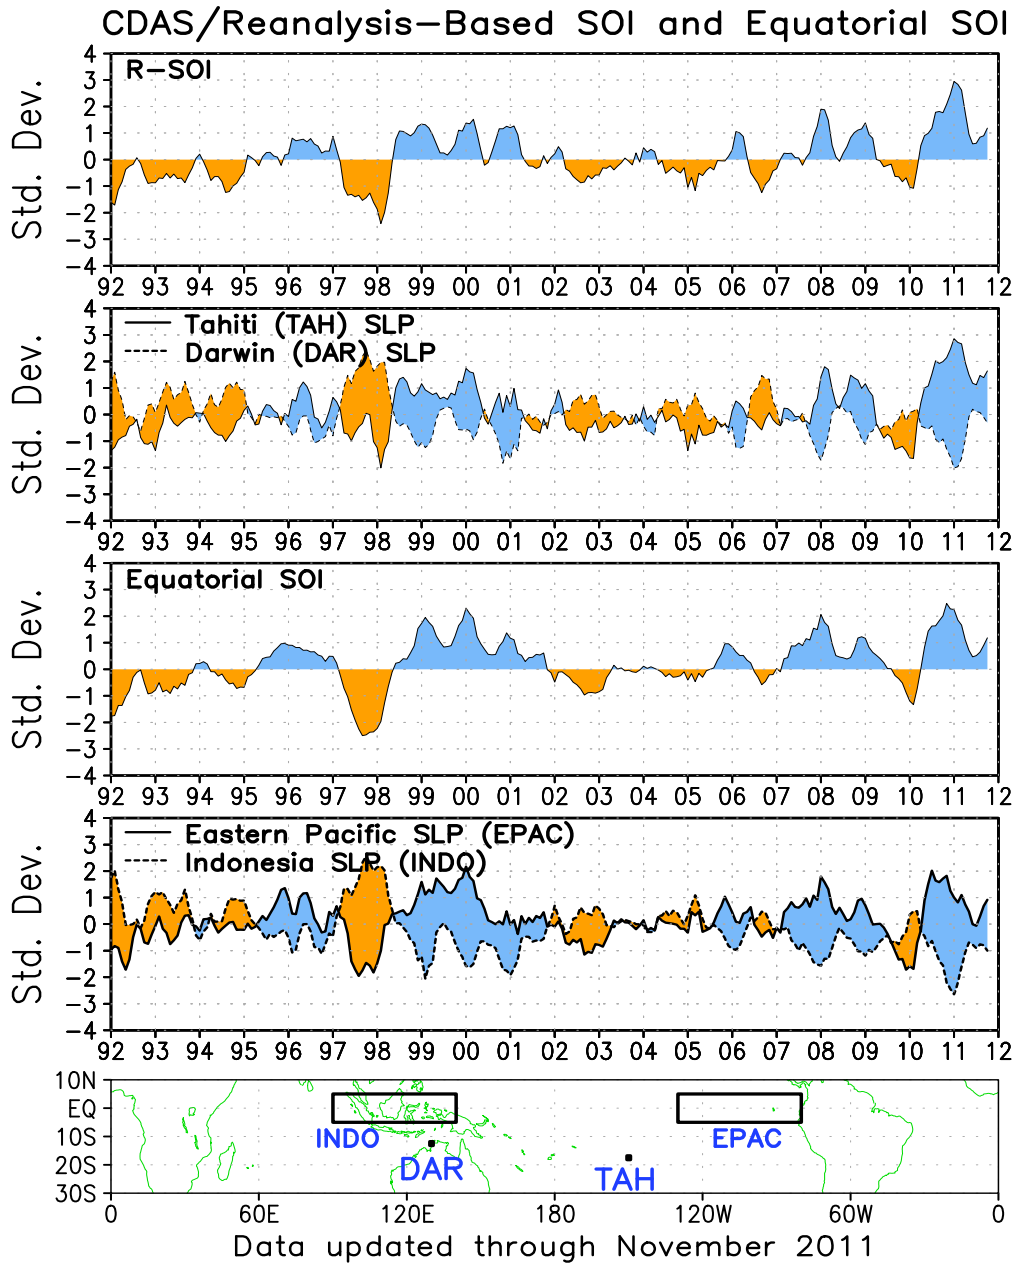

FIGURE T2. Three-month running mean of a CDAS/Reanalysis-derived (a) Southern Oscillation Index (RSOI), (b) standardized pressure anomalies near Tahiti (solid) and Darwin (dashed), (c) an equatorial SOI ([EPAC] - [INDO]), and (d) standardized equatorial pressure anomalies for (EPAC) (solid) and (INDO) (dashed). Anomalies are departures from the 1981-2010 base period means and are normalized by the mean annual standard deviation. The equatorial SOI is calculated as the normalized difference between the standardized anomalies averaged between 5°N–5°S, 80°W–130°W (EPAC) and 5°N–5°S, 90°E–140°E (INDO).

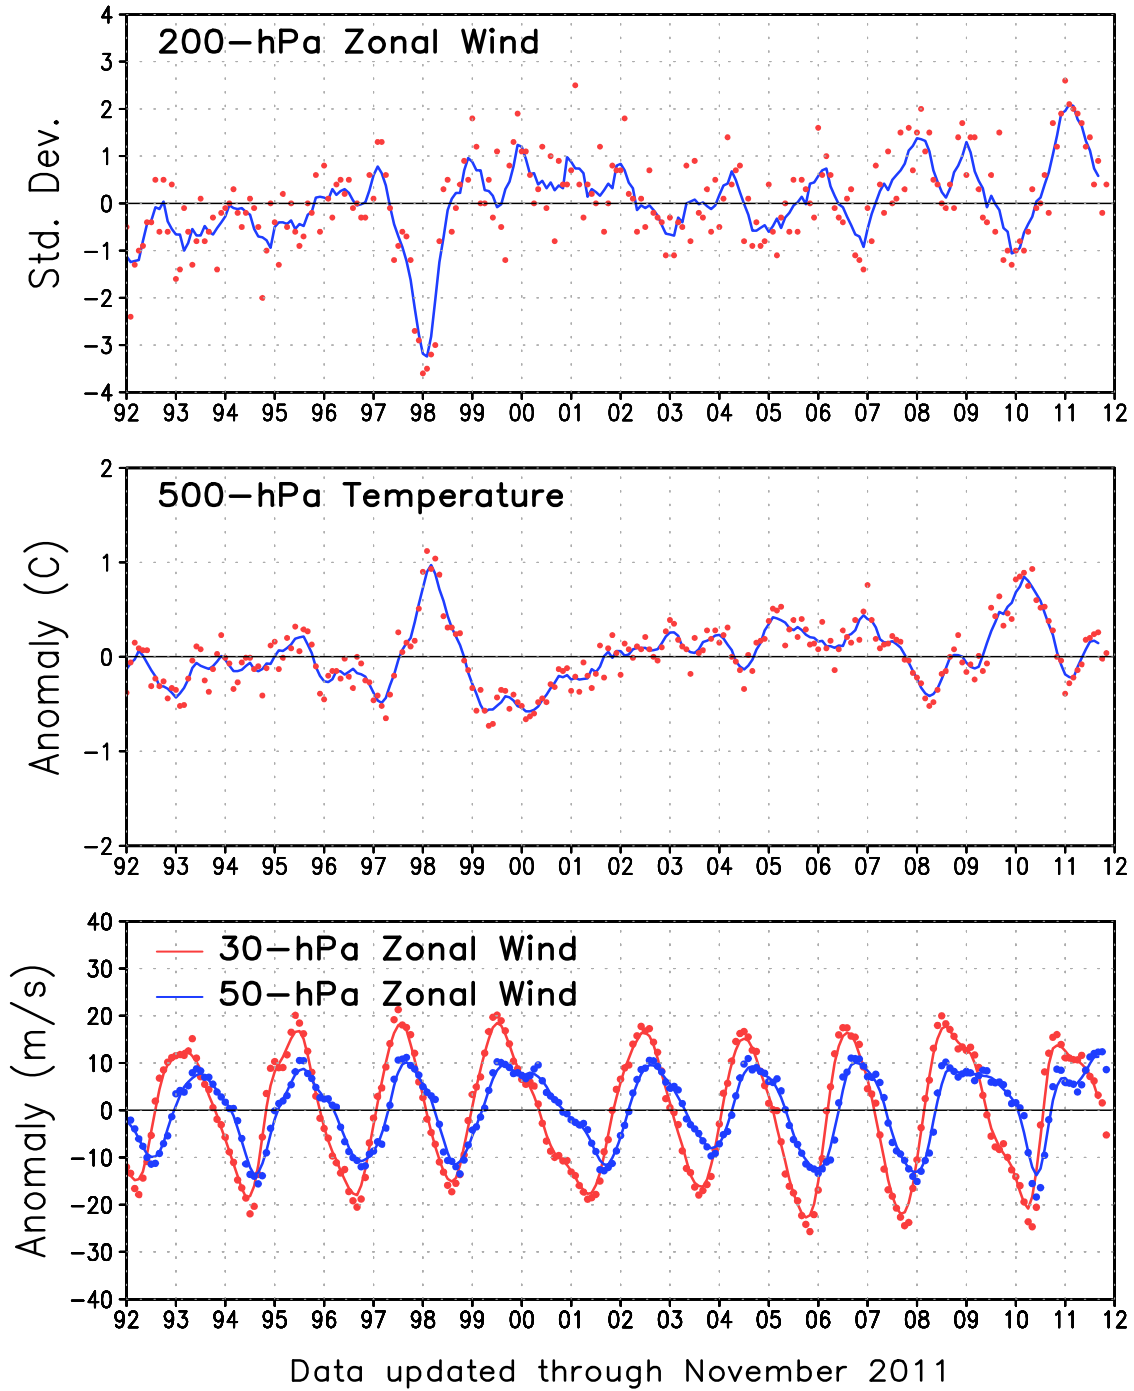

FIGURE T3. Five-month running mean (solid lines) and individual monthly mean (dots) of the 200-hPa zonal wind anomalies averaged over the area 5N-5S, 165W-110W (top), the 500-hPa virtual temperature anomalies averaged over the latitude band 20N-20S (middle), and the equatorial zonally-averaged zonal wind anomalies at 30-hPa (red) and 50-hPa (blue) (bottom). In the top panel, anomalies are normalized by the mean annual standard deviation. Anomalies are departures from the 1981-2010 base period means. The x-axis labels are centered on January.

FIGURE T4. Five-month running mean (solid line) and individual monthly mean (dots) of the standardized 850-hPa zonal wind anomaly index in the latitude belt 5N-5S for 135E-180 (top), 175W-140W (middle) and 135W-120W (bottom). Anomalies are departures from the 1981-2010 base period means and are normalized by the mean annual standard deviation. The x-axis labels are centered on January. Positive (negative) values indicate easterly (westerly) anomalies.

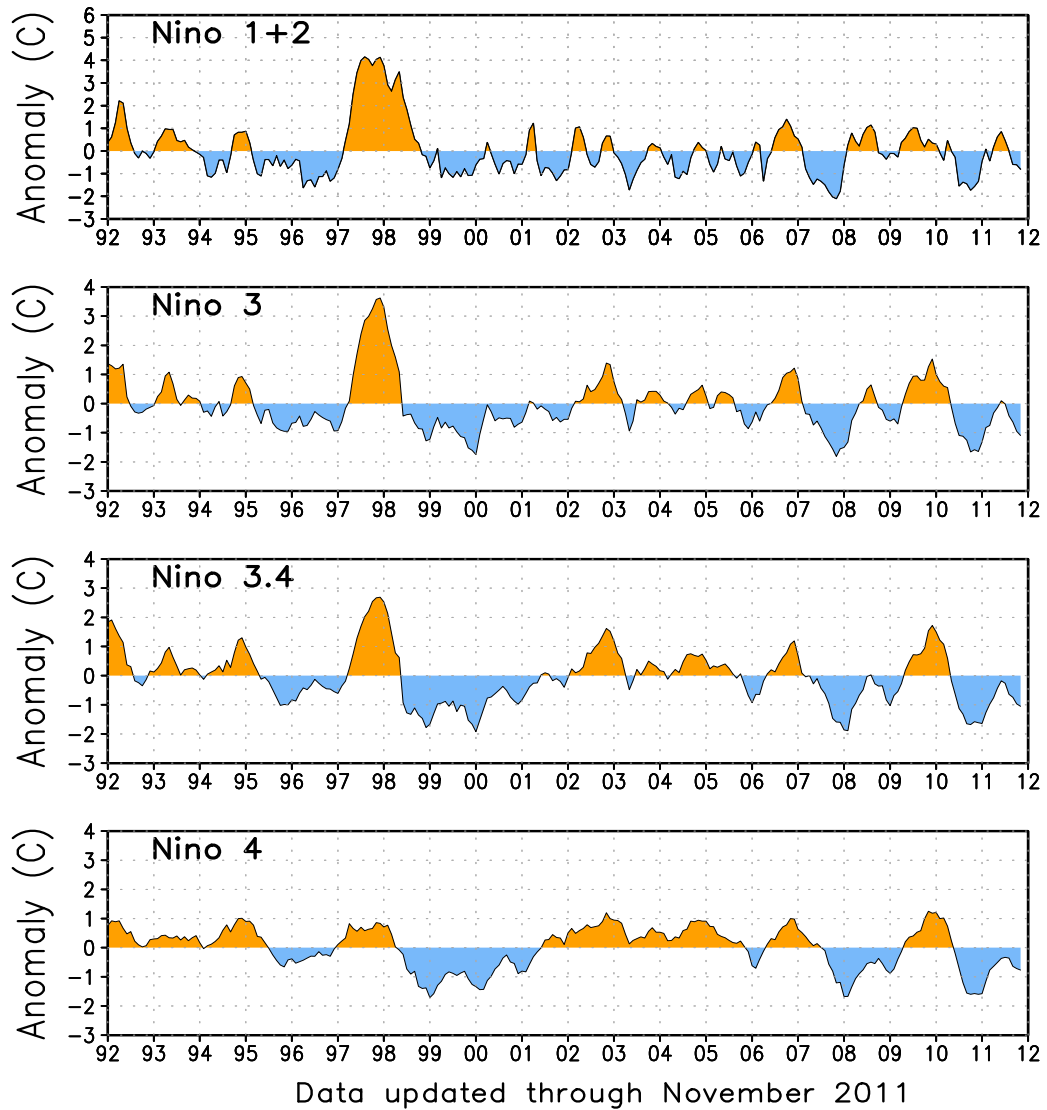

FIGURE T5. Niño region indices, calculated as the area-averaged sea surface temperature anomalies (C) for the specified region. The Niño 1+2 region (top) covers the extreme eastern equatorial Pacific between 0-10S, 90W-80W. The Niño-3 region (2nd from top) spans the eastern equatorial Pacific between 5N-5S, 150W-90W. The Niño 3.4 region (3rd from top) spans the east-central equatorial Pacific between 5N-5S, 170W-120W. The Niño 4 region (bottom) spans the date line and covers the area 5N-5S, 160E-150W. Anomalies are departures from the 1981-2010 base period monthly means (*Smith and Reynolds 1998, J. Climate, 11, 3320-3323*). Monthly values of each index are also displayed in [Table 2](#).

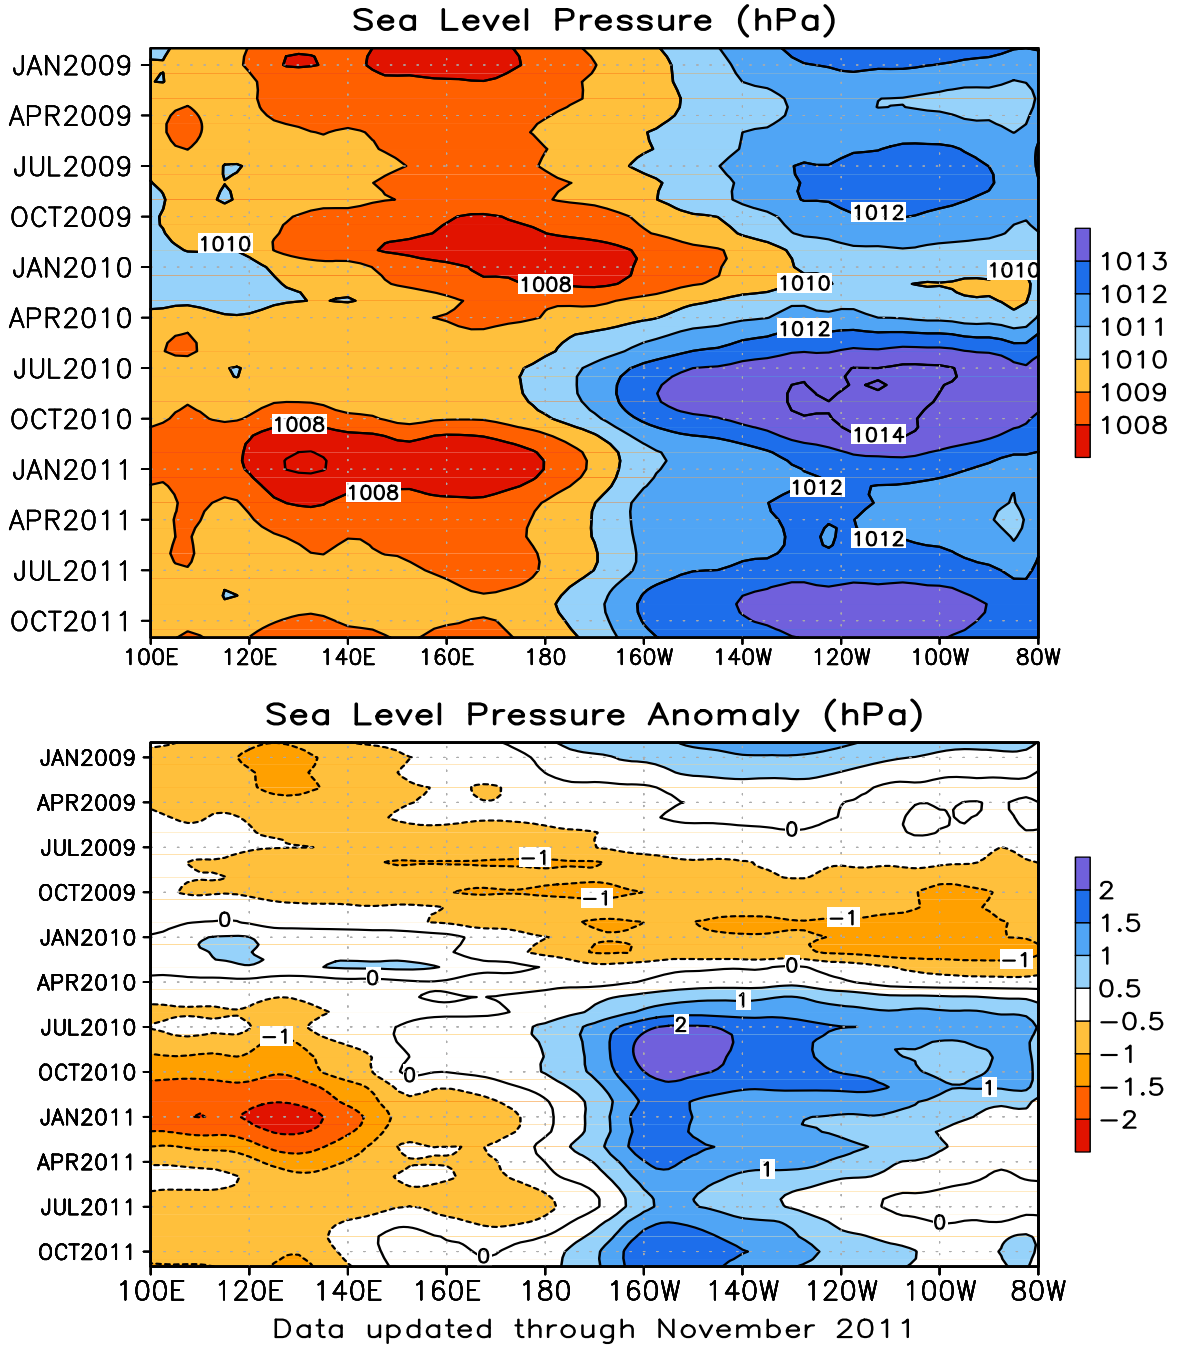

FIGURE T6. Time-longitude section of mean (top) and anomalous (bottom) sea level pressure (SLP) averaged between 5N-5S (CDAS/Reanalysis). Contour interval is 1.0 hPa (top) and 0.5 hPa (bottom). Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1981-2010 base period monthly means. The data are smoothed temporally using a 3-month running average.

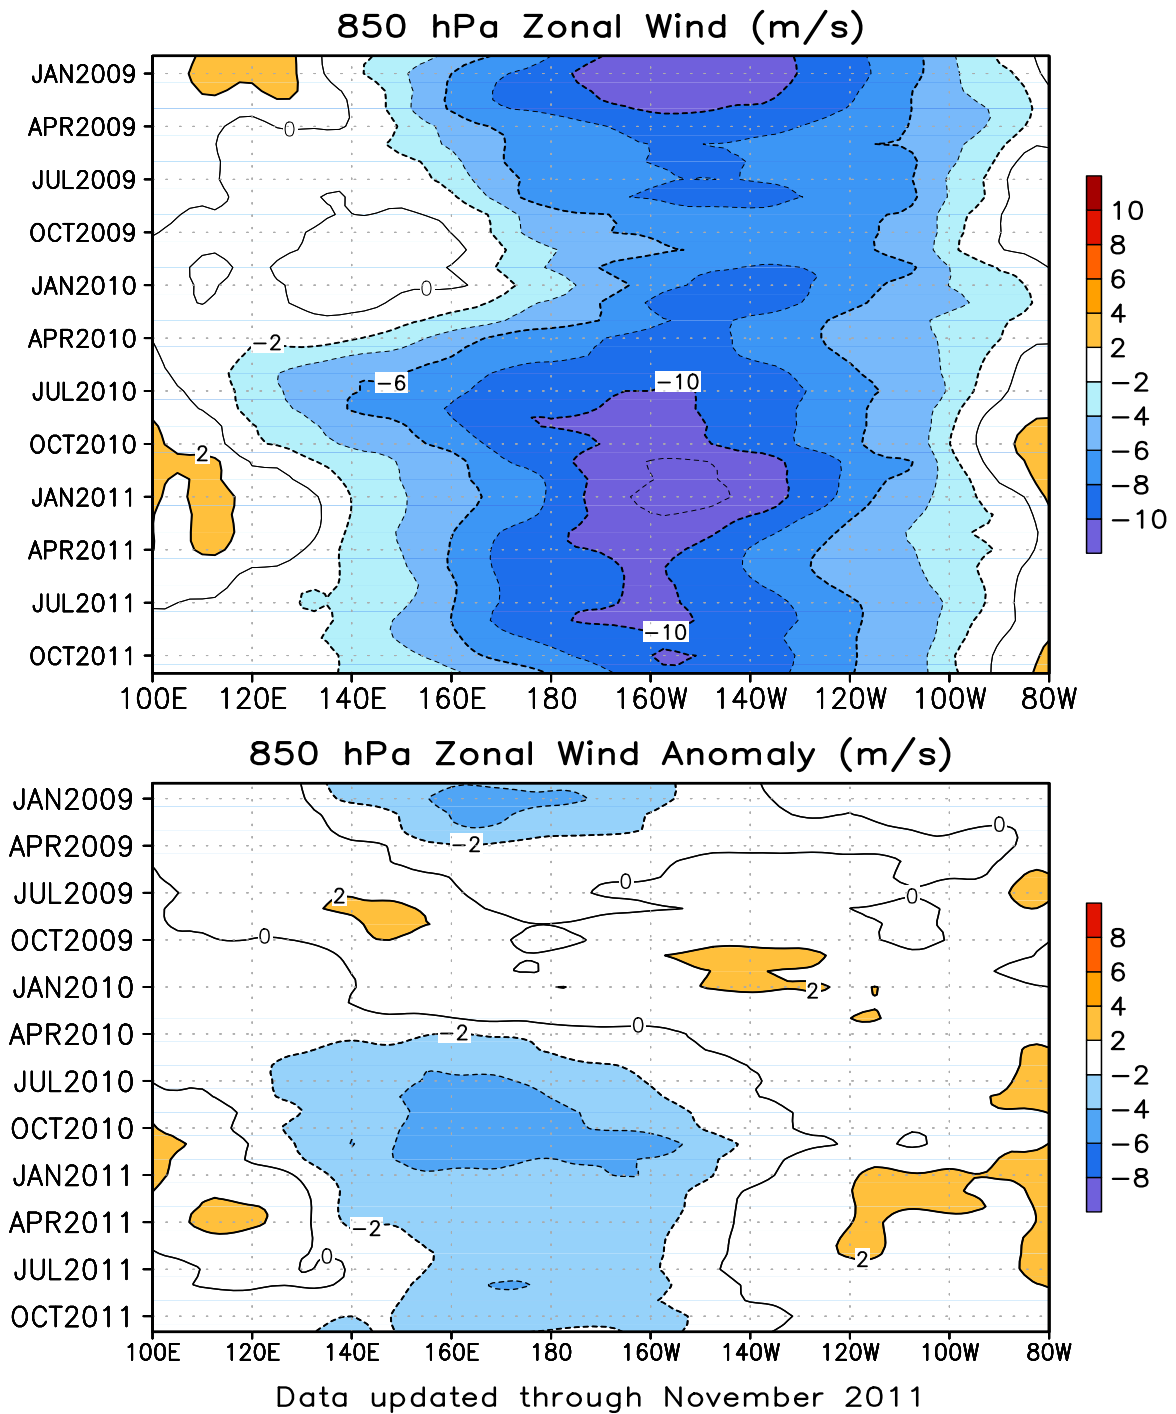

FIGURE T7. Time-longitude section of mean (top) and anomalous (bottom) 850-hPa zonal wind averaged between 5N-5S (CDAS/Reanalysis). Contour interval is  $2 \text{ ms}^{-1}$ . Blue shading and dashed contours indicate easterlies (top) and easterly anomalies (bottom). Anomalies are departures from the 1981-2010 base period monthly means. The data are smoothed temporally using a 3-month running average.

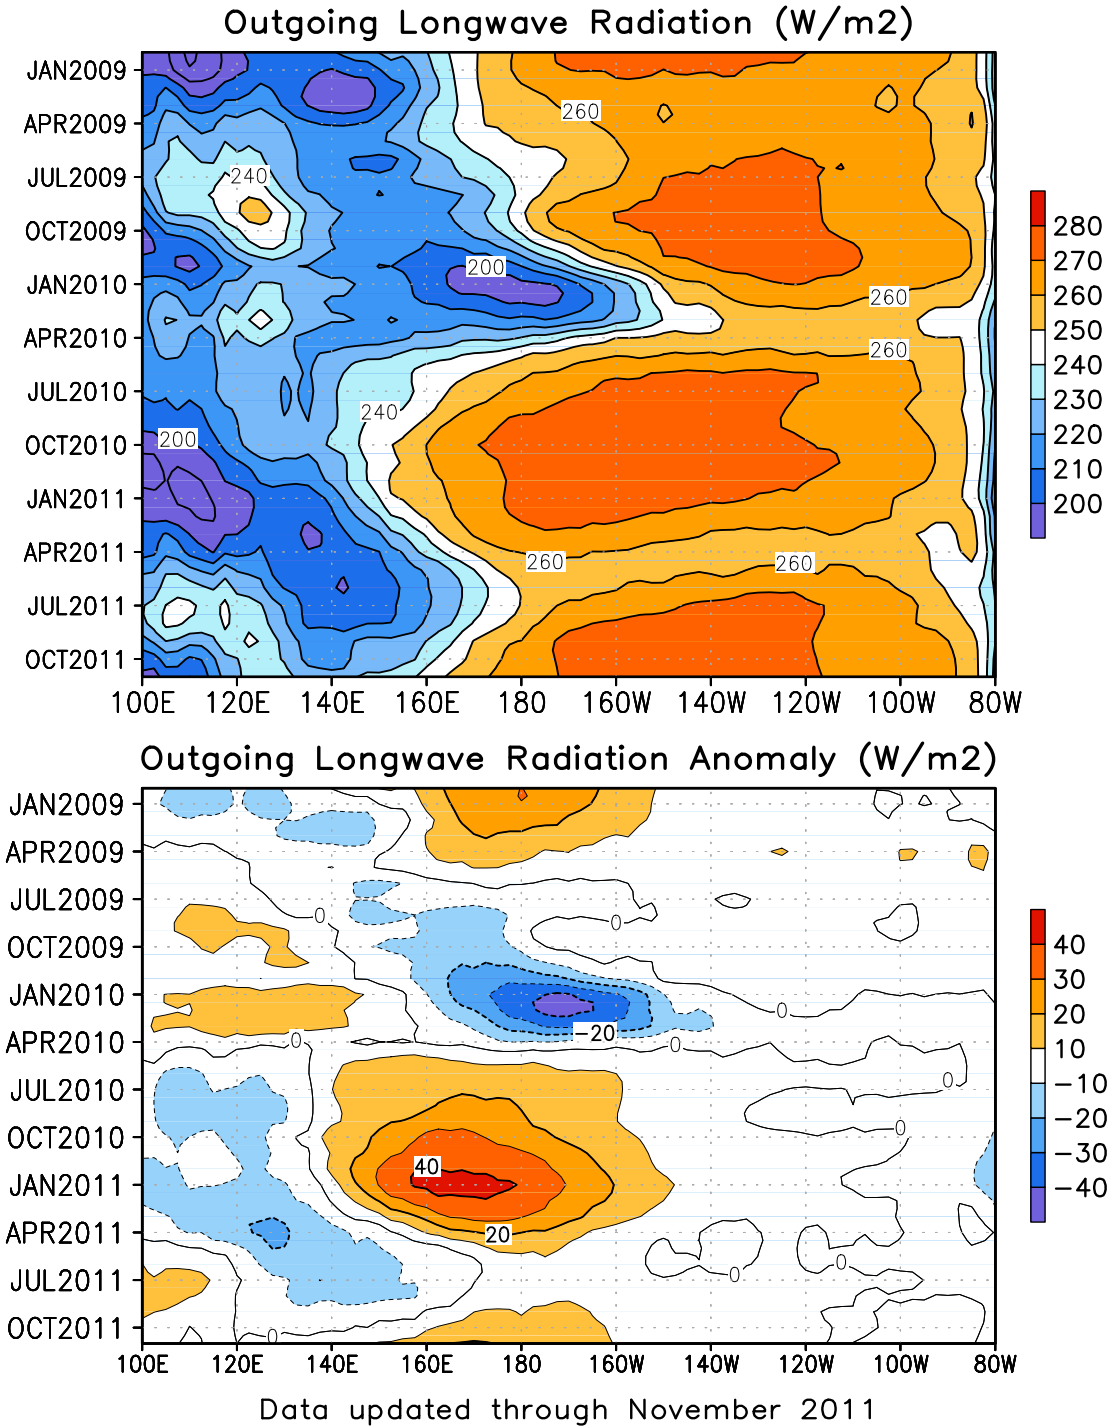

FIGURE T8. Time-longitude section of mean (top) and anomalous (bottom) outgoing longwave radiation (OLR) averaged between 5N-5S. Contour interval is 10 Wm<sup>-2</sup>. Dashed contours in bottom panel indicate negative OLR anomalies. Anomalies are departures from the 1981-2010 base period monthly means. The data are smoothed temporally using a 3-month running average.

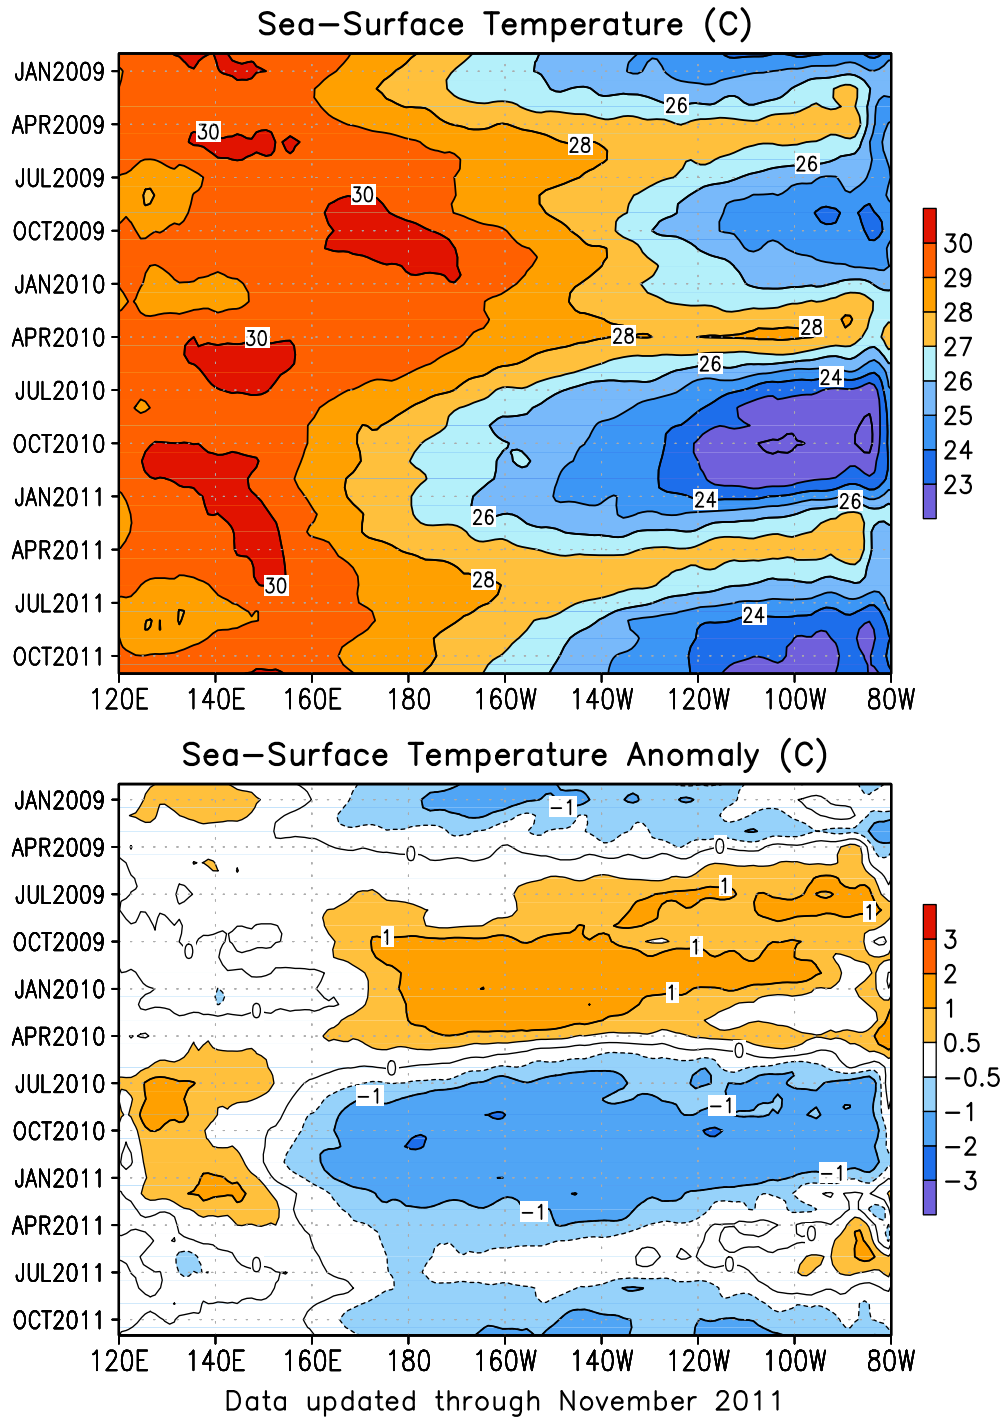

FIGURE T9. Time-longitude section of monthly mean (top) and anomalous (bottom) sea surface temperature (SST) averaged between 5N-5S. Contour interval is 1C (top) and 0.5C (bottom). Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1981-2010 base period means (Smith and Reynolds 1998, *J. Climate*, **11**, 3320-3323).

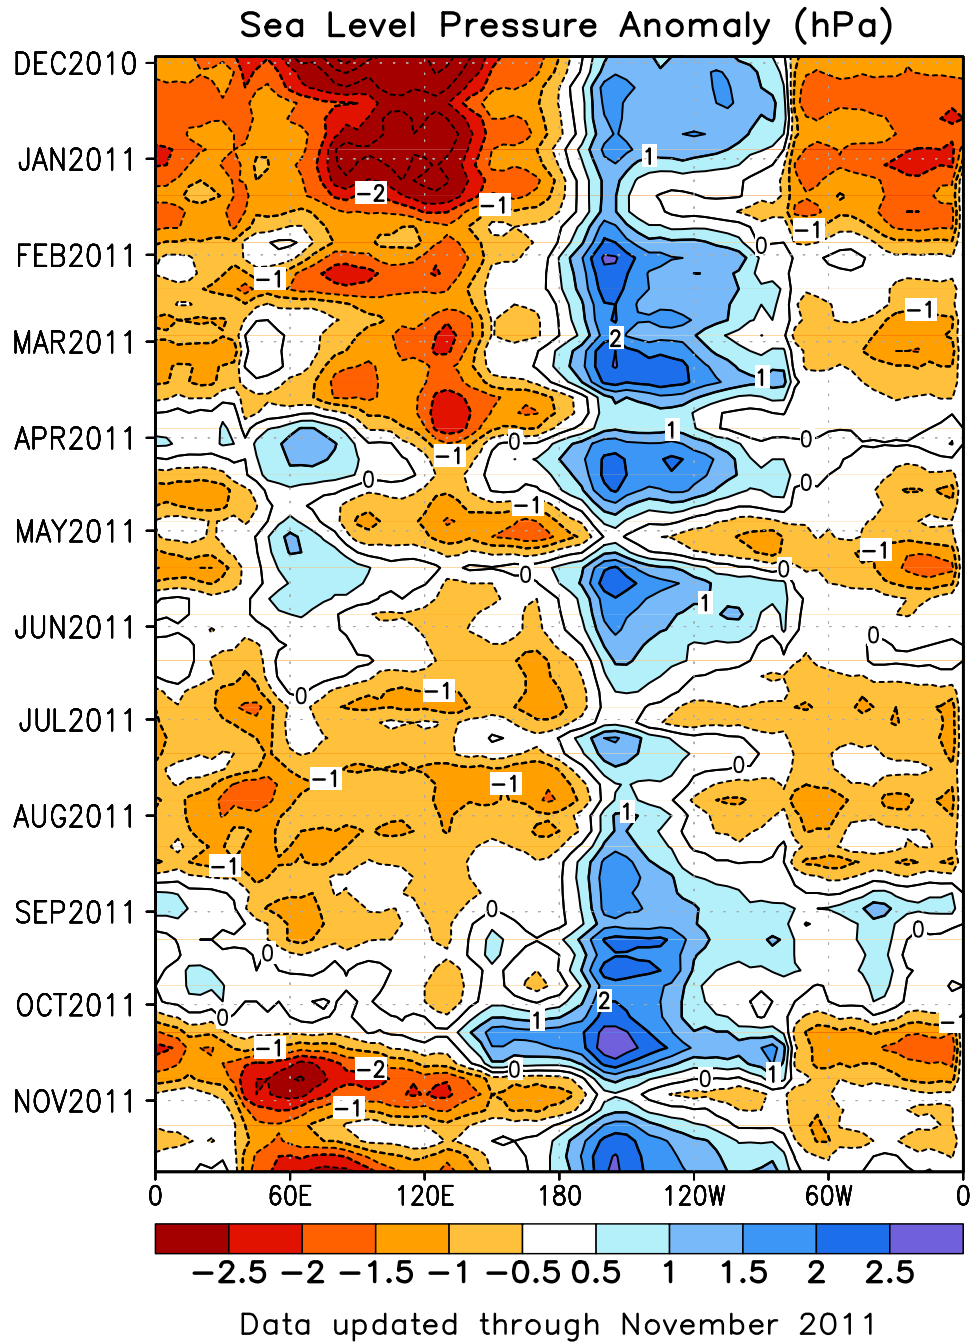

FIGURE T10. Time-longitude section of anomalous sea level pressure (hPa) averaged between 5N-5S (CDAS/Re-analysis). Contour interval is 1 hPa. Dashed contours indicate negative anomalies. Anomalies are departures from the 1981-2010 base period pentad means. The data are smoothed temporally using a 3-point running average.

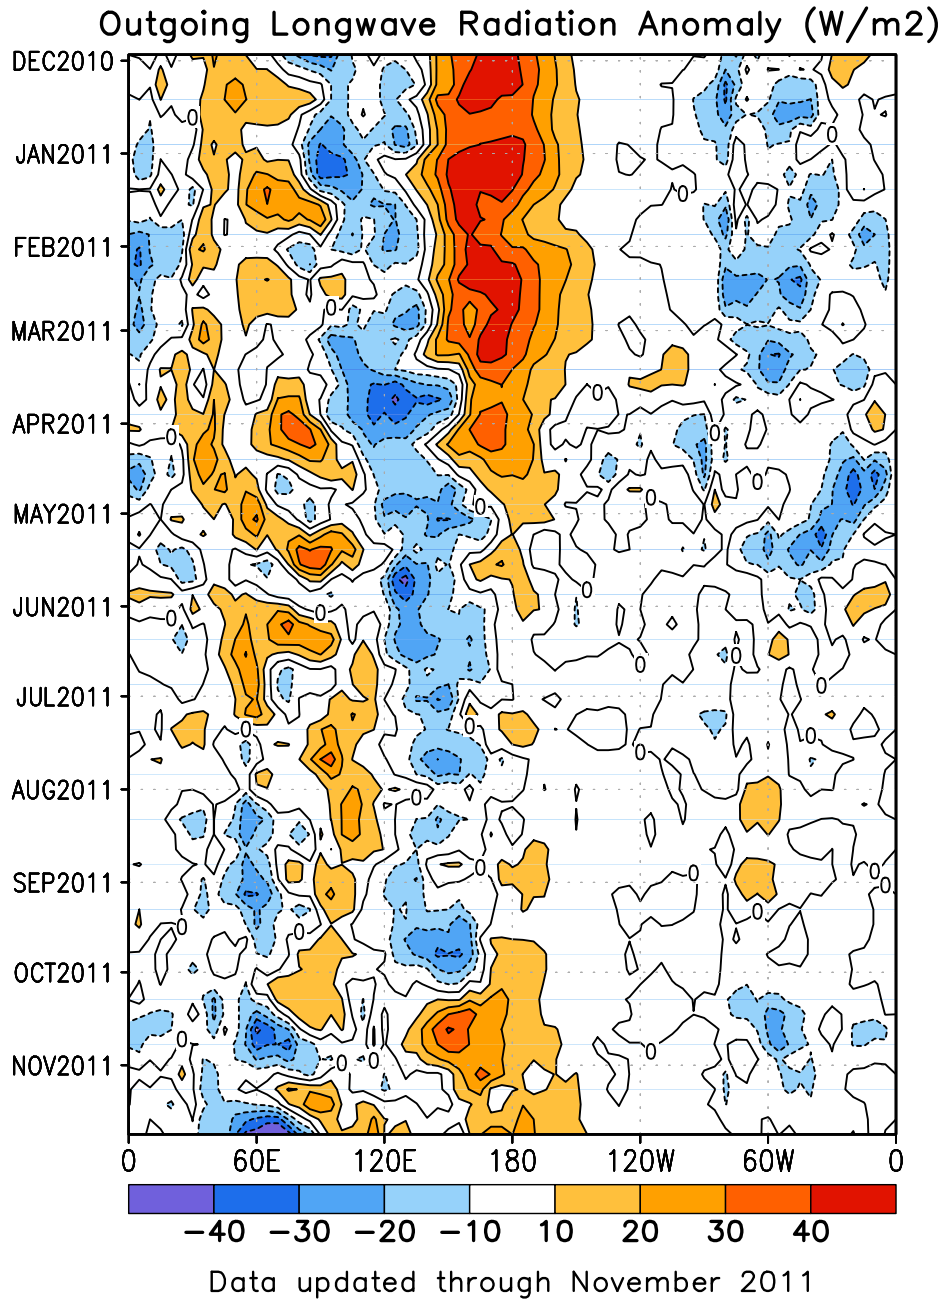

FIGURE T11. Time-longitude section of anomalous outgoing longwave radiation averaged between 5N-5S. Contour interval is 15 Wm<sup>-2</sup>. Dashed contours indicate negative anomalies. Anomalies are departures from the 1981-2010 base period pentad means. The data are smoothed temporally using a 3-point running average.

FIGURE T12. Time-longitude section of anomalous 200-hPa velocity potential averaged between 5N-5S (CDAS/Re-analysis). Contour interval is  $3 \times 10^6 \text{ m}^2\text{s}^{-1}$ . Dashed contours indicate negative anomalies. Anomalies are departures from the 1981-2010 base period pentad means. The data are smoothed temporally using a 3-point running average.

FIGURE T13. Time-longitude section of anomalous 850-hPa zonal wind averaged between 5N-5S (CDAS/Reanalysis). Contour interval is  $2 \text{ m s}^{-1}$ . Dashed contours indicate negative anomalies. Anomalies are departures from the 1981-2010 base period pentad means. The data are smoothed temporally by using a 3-point running average.

FIGURE T14. Equatorial time-height section of anomalous zonally-averaged zonal wind ( $\text{m s}^{-1}$ ) (CDAS/Reanalysis). Contour interval is  $10 \text{ m s}^{-1}$ . Anomalies are departures from the 1981-2010 base period monthly means.

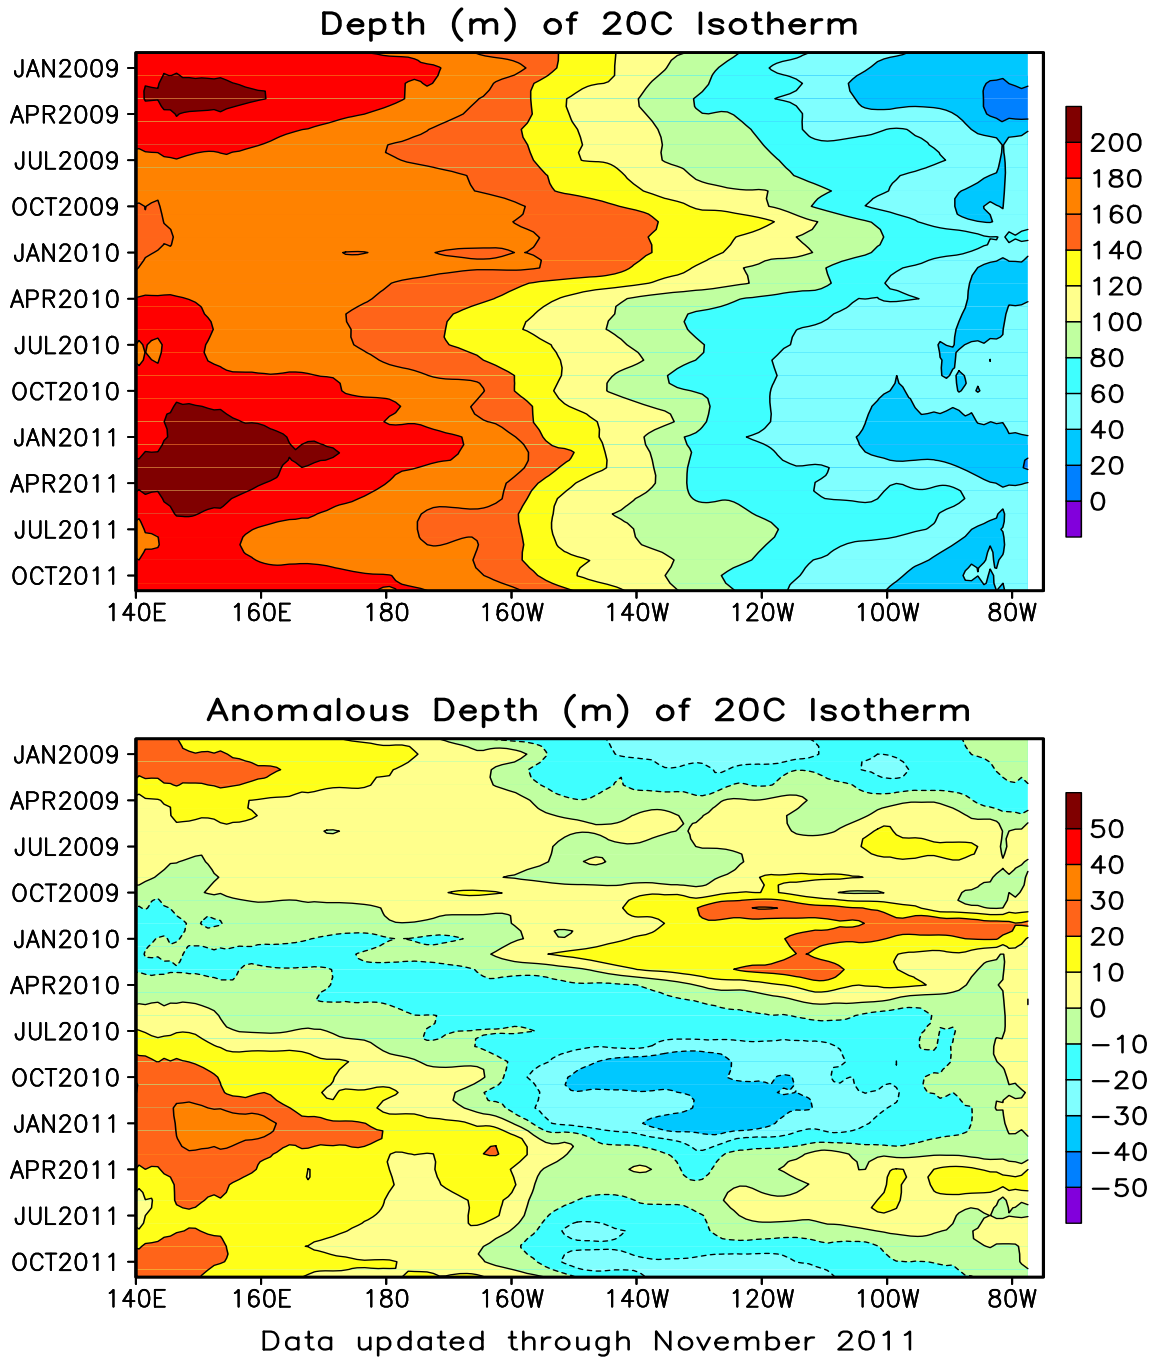

FIGURE T15. Mean (top) and anomalous (bottom) depth of the 20C isotherm averaged between 5N-5S in the Pacific Ocean. Data are derived from the NCEP's global ocean data assimilation system which assimilates oceanic observations into an oceanic GCM (Behringer, D. W., and Y. Xue, 2004: Evaluation of the global ocean data assimilation system at NCEP: The Pacific Ocean. AMS 84th Annual Meeting, Seattle, Washington, 11-15). The contour interval is 10 m. Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1981-2010 base period means.

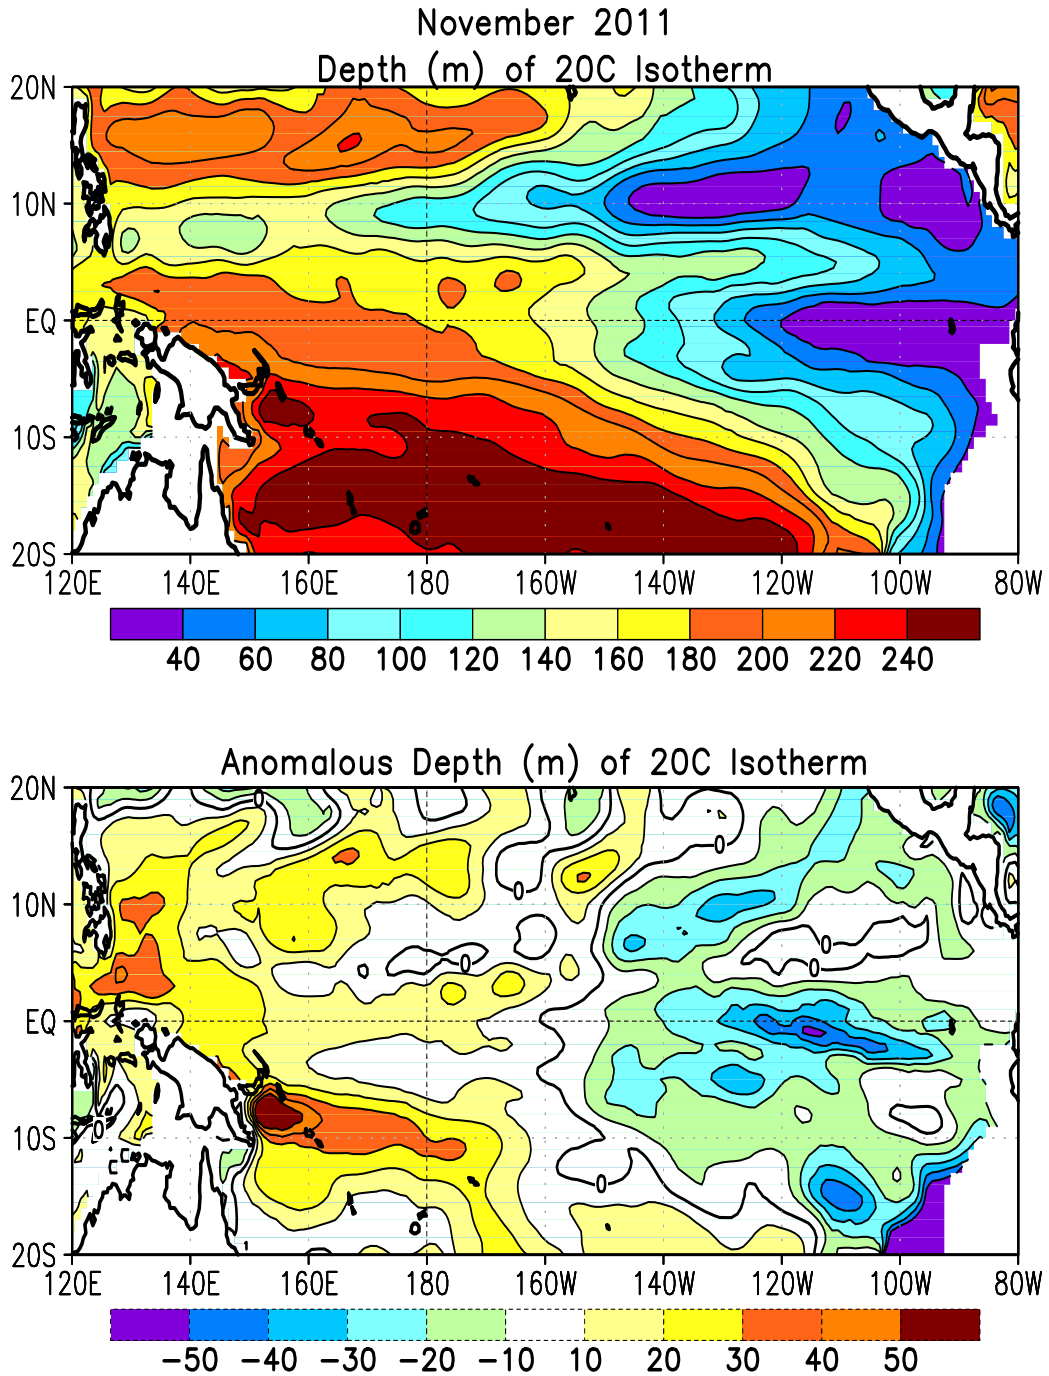

FIGURE T16. Mean (top) and anomalous (bottom) depth of the 20°C isotherm for NOV 2011. Contour interval is 40 m (top) and 10 m (bottom). Dashed contours in bottom panel indicate negative anomalies. Data are derived from the NCEP’s global ocean data assimilation system version 2 which assimilates oceanic observations into an oceanic GCM (Xue, Y. and Behringer, D.W., 2006: Operational global ocean data assimilation system at NCEP, to be submitted to BAMS). Anomalies are departures from the 1981–2010 base period means.

November 2011: Depth–Longitude Section  
Equatorial Ocean Temperatures (C)

Equatorial Ocean Temperature Anomalies (C)

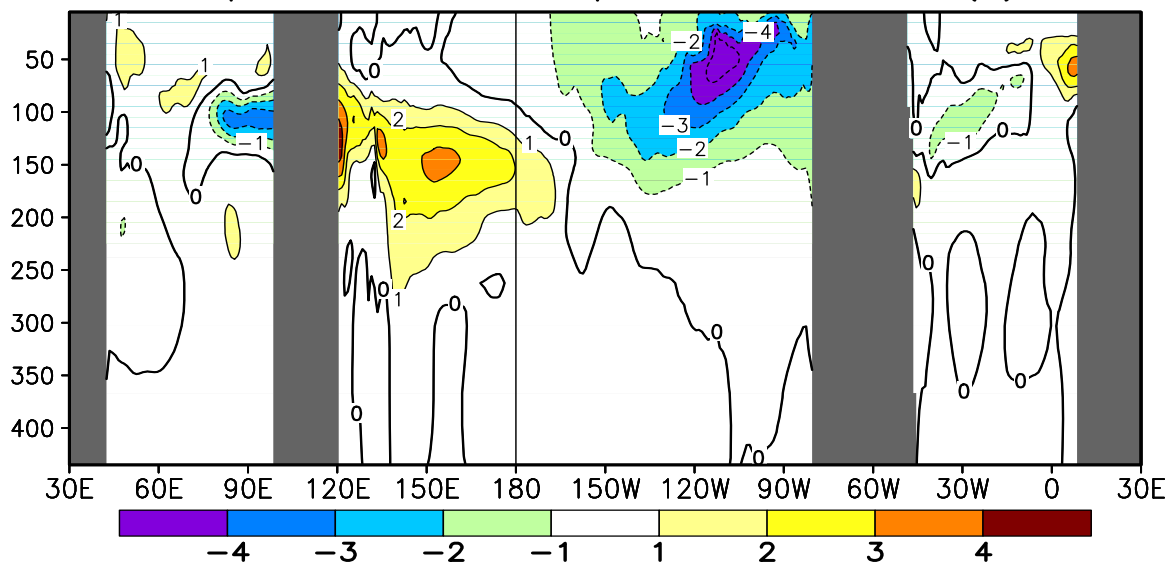

FIGURE T17. Equatorial depth–longitude section of ocean temperature (top) and ocean temperature anomalies (bottom) for NOV 2011. Contour interval is 1°C. Dashed contours in bottom panel indicate negative anomalies. Data are derived from the NCEP’s global ocean data assimilation system version 2 which assimilates oceanic observations into an oceanic GCM (Xue, Y. and Behringer, D.W., 2006: Operational global ocean data assimilation system at NCEP, to be submitted to BAMS). Anomalies are departures from the 1981–2010 base period means.

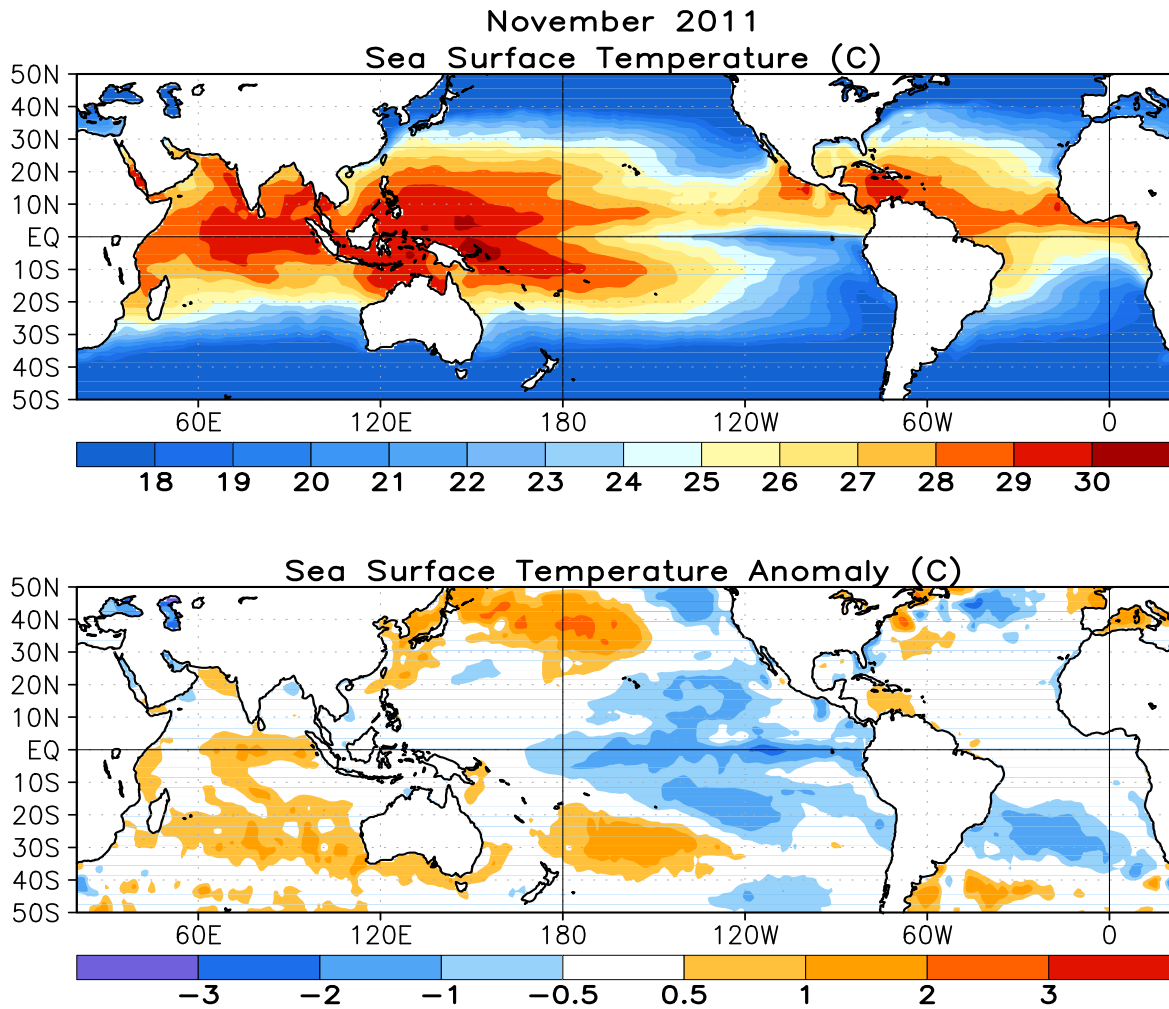

FIGURE T18. Mean (top) and anomalous (bottom) sea surface temperature (SST). Anomalies are departures from the 1981-2010 base period monthly means (Smith and Reynolds 1998, *J. Climate*, **11**, 3320-3323).

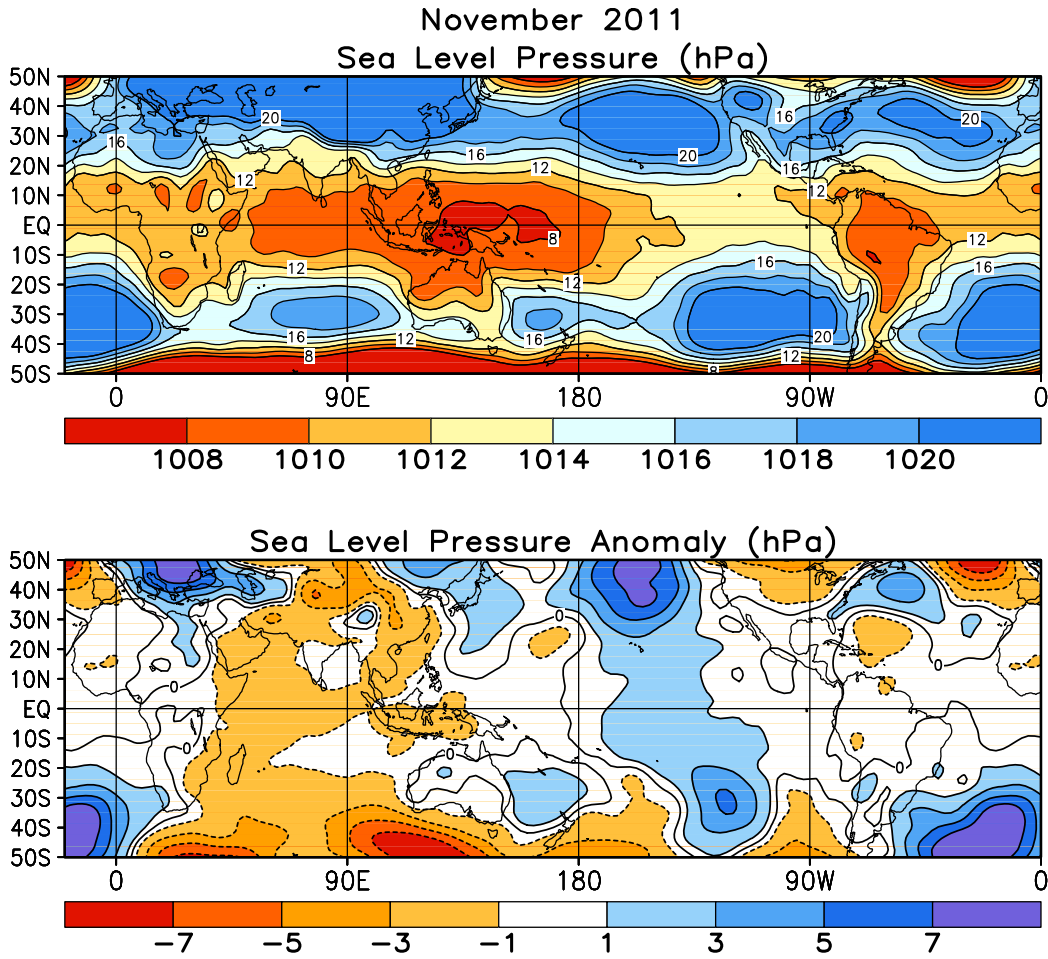

FIGURE T19. Mean (top) and anomalous (bottom) sea level pressure (SLP) (CDAS/Reanalysis). In top panel, 1000 hPa has been subtracted from contour labels, contour interval is 2 hPa, and values below 1000 hPa are indicated by dashed contours. In bottom panel, anomaly contour interval is 1 hPa and negative anomalies are indicated by dashed contours. Anomalies are departures from the 1981-2010 base period monthly means.

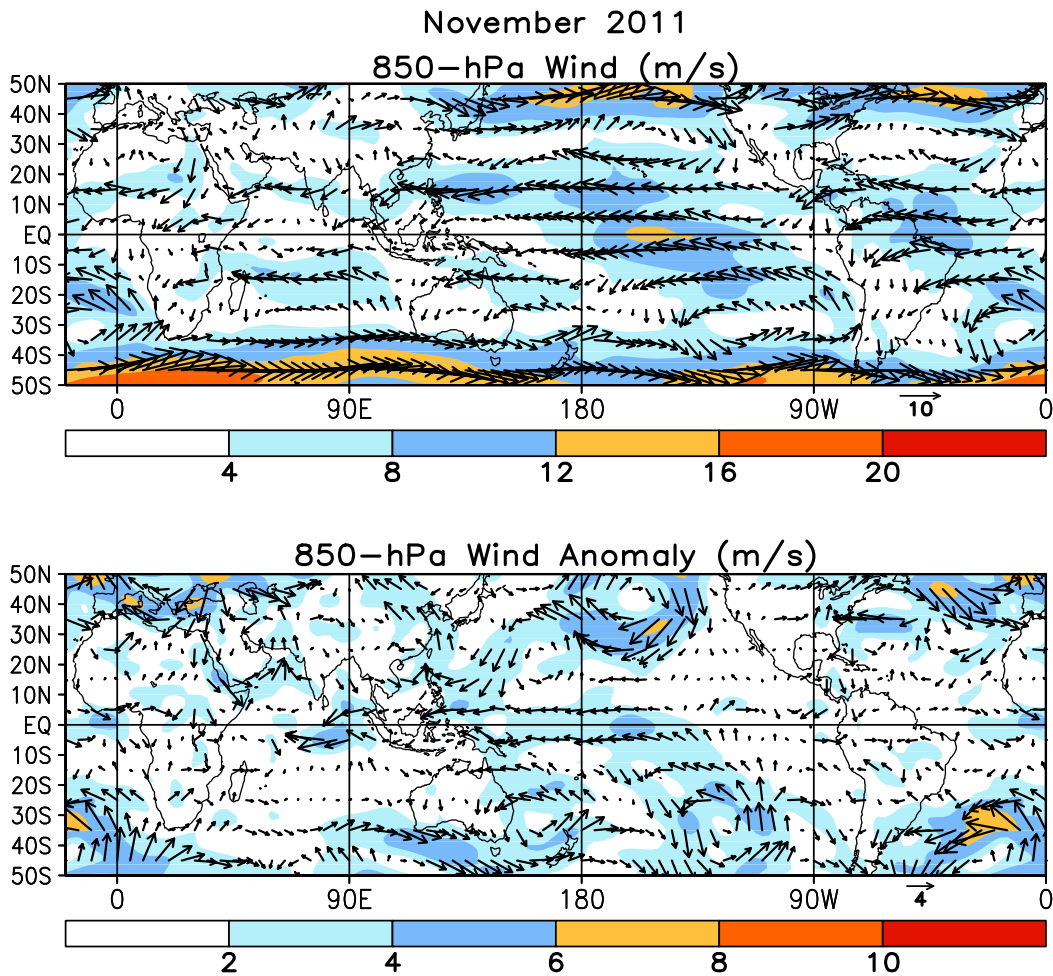

FIGURE T20. Mean (top) and anomalous (bottom) 850-hPa vector wind (CDAS/Reanalysis) for NOV 2011. Contour interval for isotachs is  $4 \text{ ms}^{-1}$  (top) and  $2 \text{ ms}^{-1}$  (bottom). Anomalies are departures from the 1981-2010 base period monthly means.

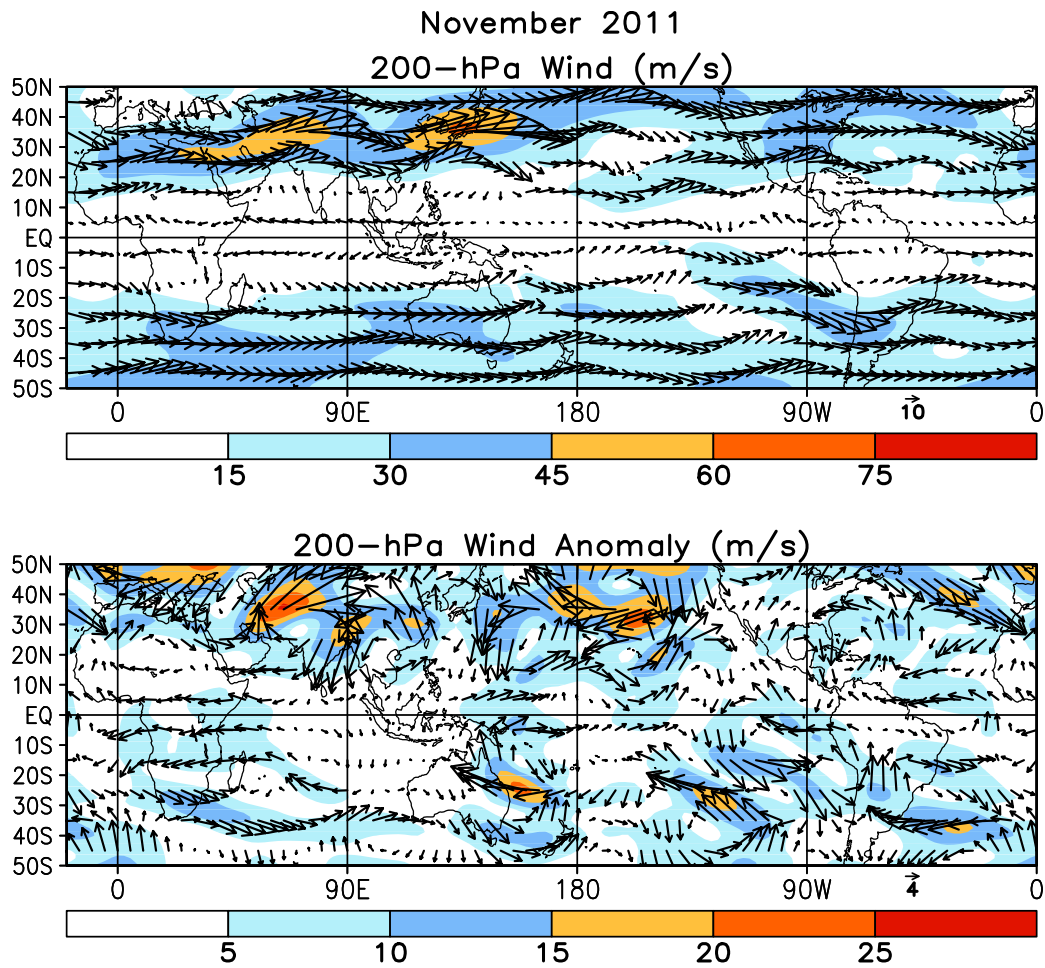

FIGURE T21. Mean (top) and anomalous (bottom) 200-hPa vector wind (CDAS/Reanalysis) for NOV 2011. Contour interval for isotachs is  $15 \text{ ms}^{-1}$  (top) and  $5 \text{ ms}^{-1}$  (bottom). Anomalies are departures from 1981-2010 base period monthly means.

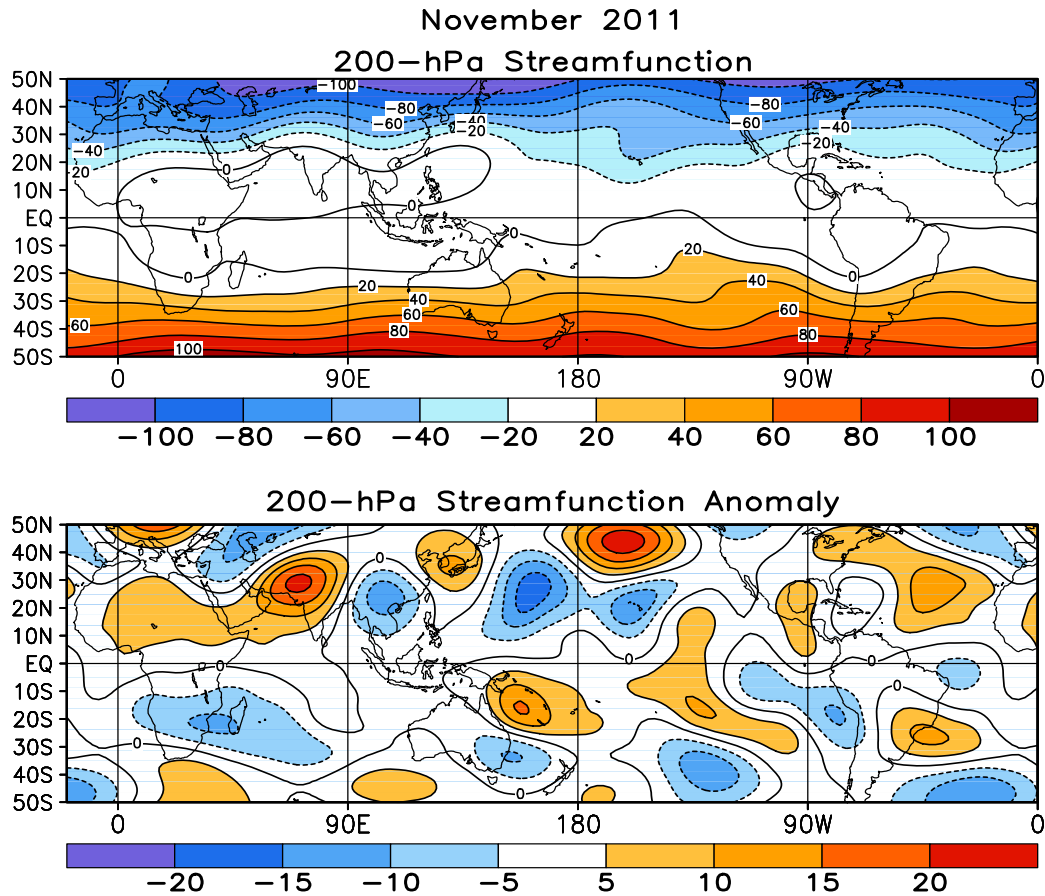

FIGURE T22. Mean (top) and anomalous (bottom) 200-hPa streamfunction (CDAS/Reanalysis). Contour interval is  $20 \times 10^6 \text{ m}^2\text{s}^{-1}$  (top) and  $5 \times 10^6 \text{ m}^2\text{s}^{-1}$  (bottom). Negative (positive) values are indicated by dashed (solid) lines. The non-divergent component of the flow is directed along the contours with speed proportional to the gradient. Thus, high (low) stream function corresponds to high (low) geopotential height in the Northern Hemisphere and to low (high) geopotential height in the Southern Hemisphere. Anomalies are departures from the 1981-2010 base period monthly means.

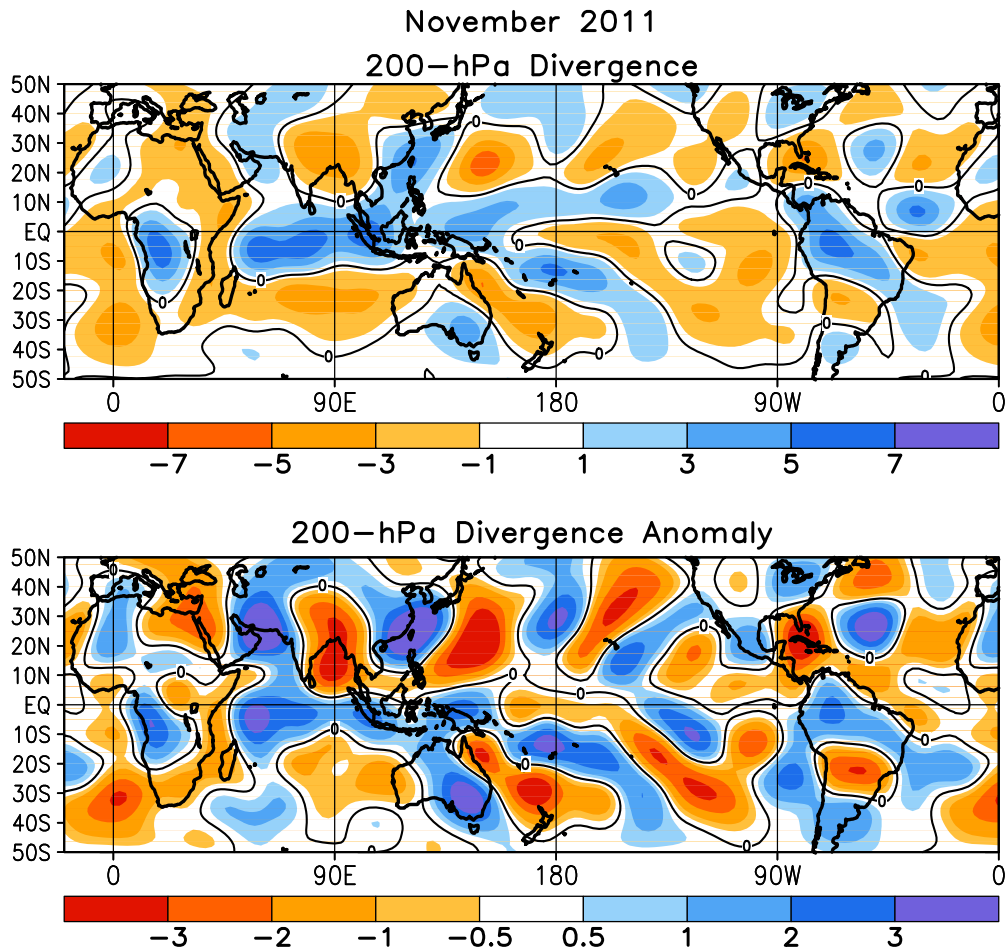

FIGURE T23. Mean (top) and anomalous (bottom) 200-hPa divergence (CDAS/Reanalysis). Divergence and anomalous divergence are shaded blue. Convergence and anomalous convergence are shaded orange. Anomalies are departures from the 1981-2010 base period monthly means.

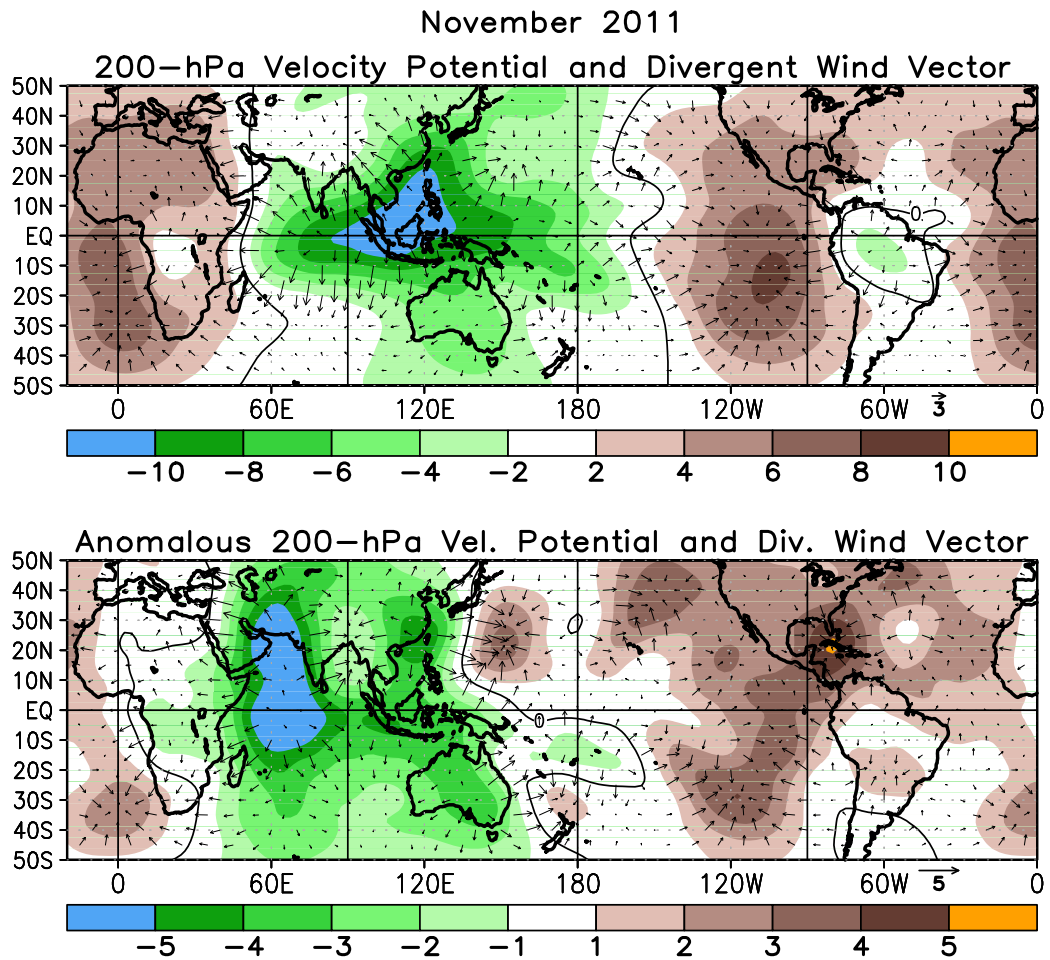

FIGURE T24. Mean (top) and anomalous (bottom) 200-hPa velocity potential ( $10^6\text{m}^2\text{s}$ ) and divergent wind (CDAS/Reanalysis). Anomalies are departures from the 1981-2010 base period monthly means.

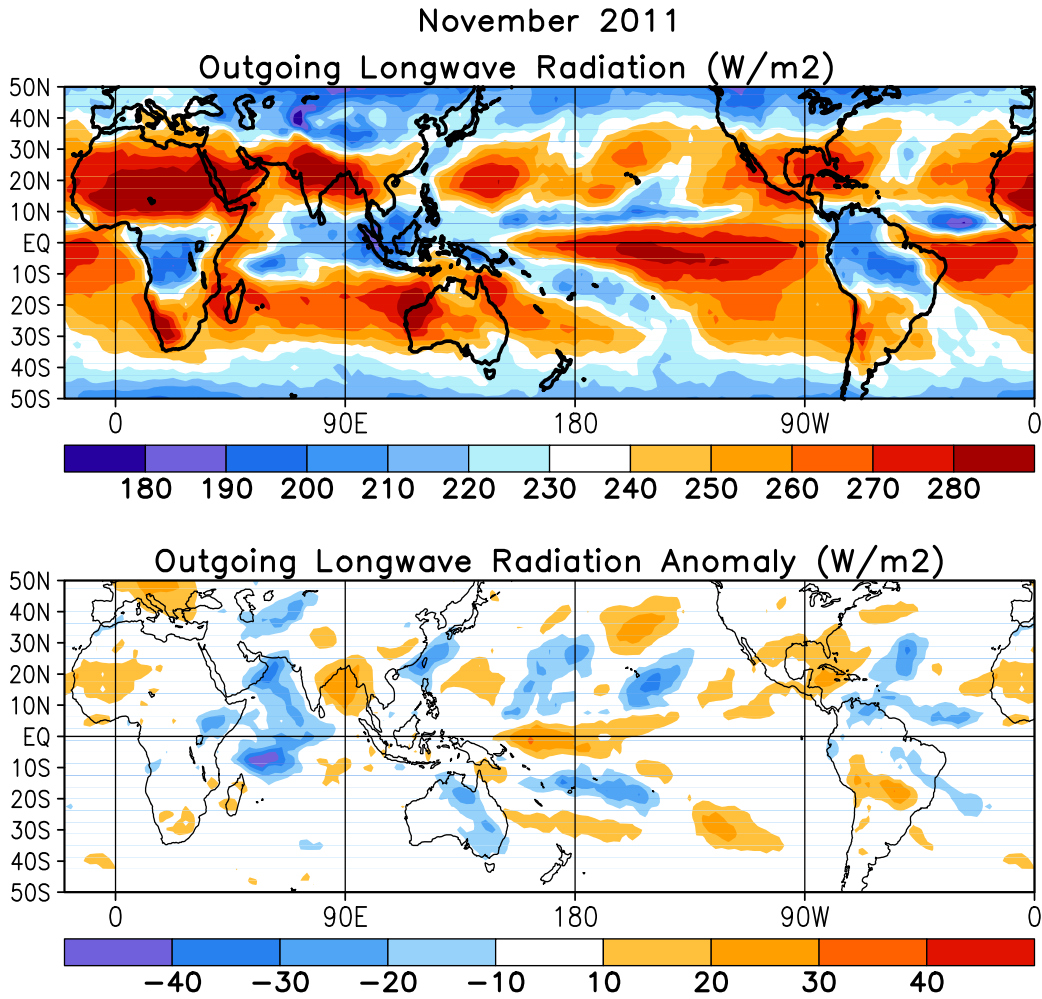

FIGURE T25. Mean (top) and anomalous (bottom) outgoing longwave radiation for NOV 2011 (NOAA 18 AVHRR IR window channel measurements by NESDIS/ORR). OLR contour interval is  $20 Wm^{-2}$  with values greater than  $280 Wm^{-2}$  indicated by dashed contours. Anomaly contour interval is  $15 Wm^{-2}$  with positive values indicated by dashed contours and light shading. Anomalies are departures from the 1981-2010 base period monthly means.

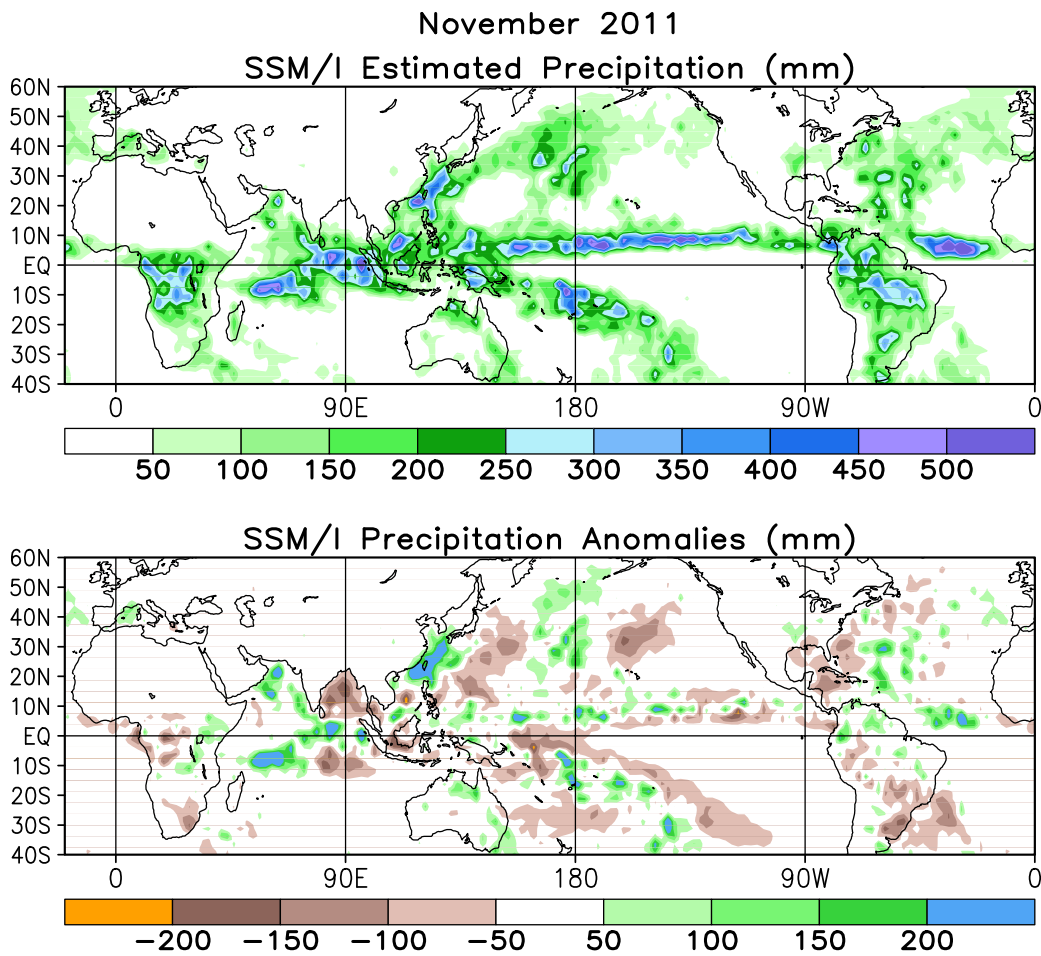

FIGURE T26. Estimated total (top) and anomalous (bottom) rainfall (mm) based on the Special Sensor Microwave/Imager (SSM/S) precipitation index (Ferraro 1997, *J. Geophys. Res.*, **102**, 16715-16735). Anomalies are computed from the SSM/I 1987-2010 base period monthly means. Anomalies have been smoothed for display purposes.

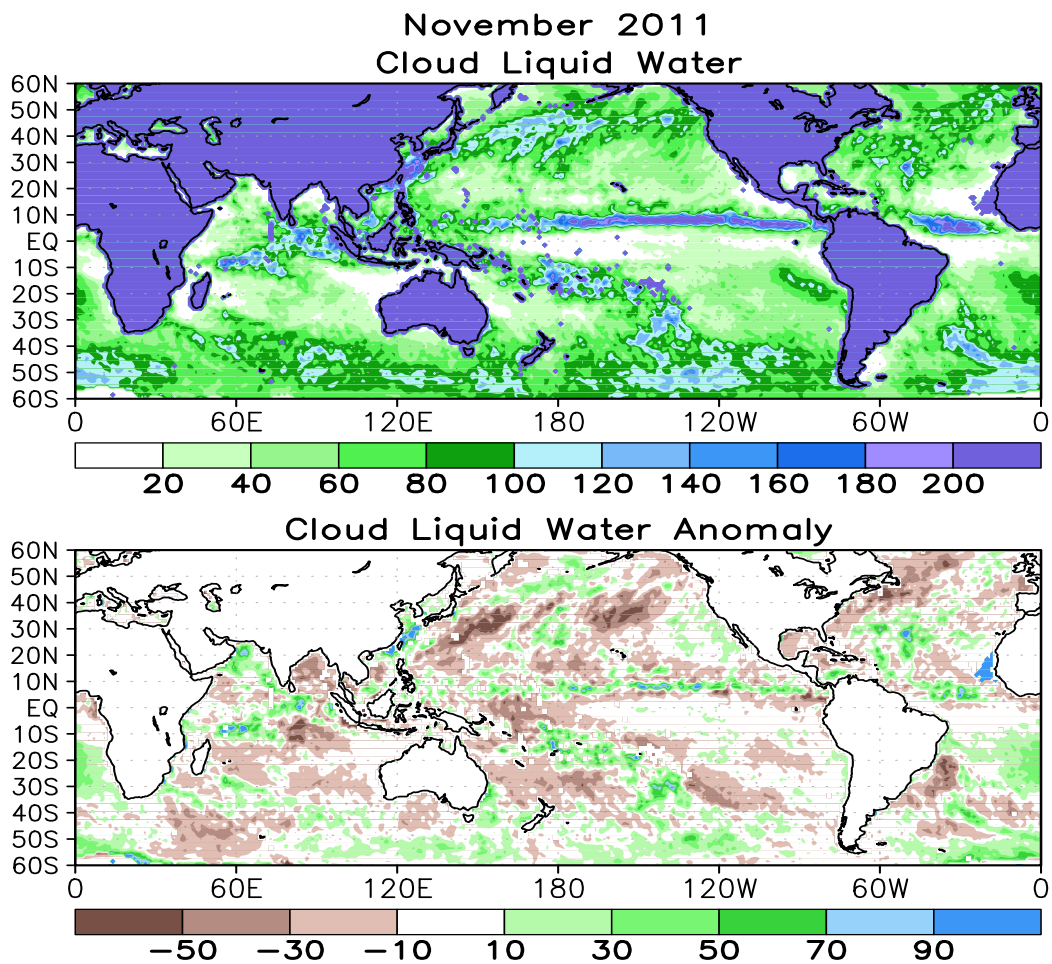

FIGURE T27. Mean (top) and anomalous (bottom) cloud liquid water ( $\text{g m}^{-2}$ ) based on the Special Sensor Microwave/Imager (SSM/I) (Weng et al 1997: *J. Climate*, **10**, 1086-1098). Anomalies are calculated from the 1987-2010 base period means.

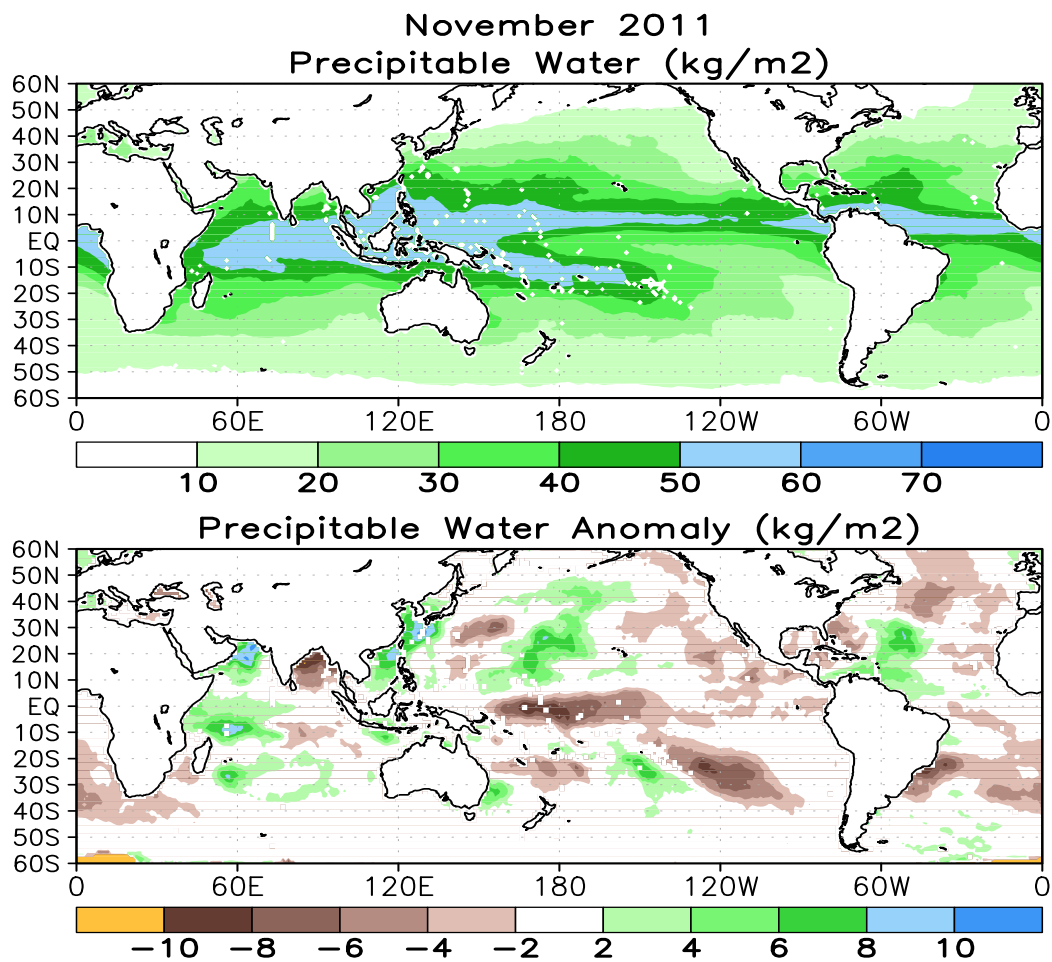

FIGURE T28. Mean (top) and anomalous (bottom) vertically integrated water vapor or precipitable water ( $\text{kg m}^{-2}$ ) based on the Special Sensor Microwave/Imager (SSM/I) (Ferraro et. al, 1996: *Bull. Amer. Meteor. Soc.*, **77**, 891-905). Anomalies are calculated from the 1987-2010 base period means.

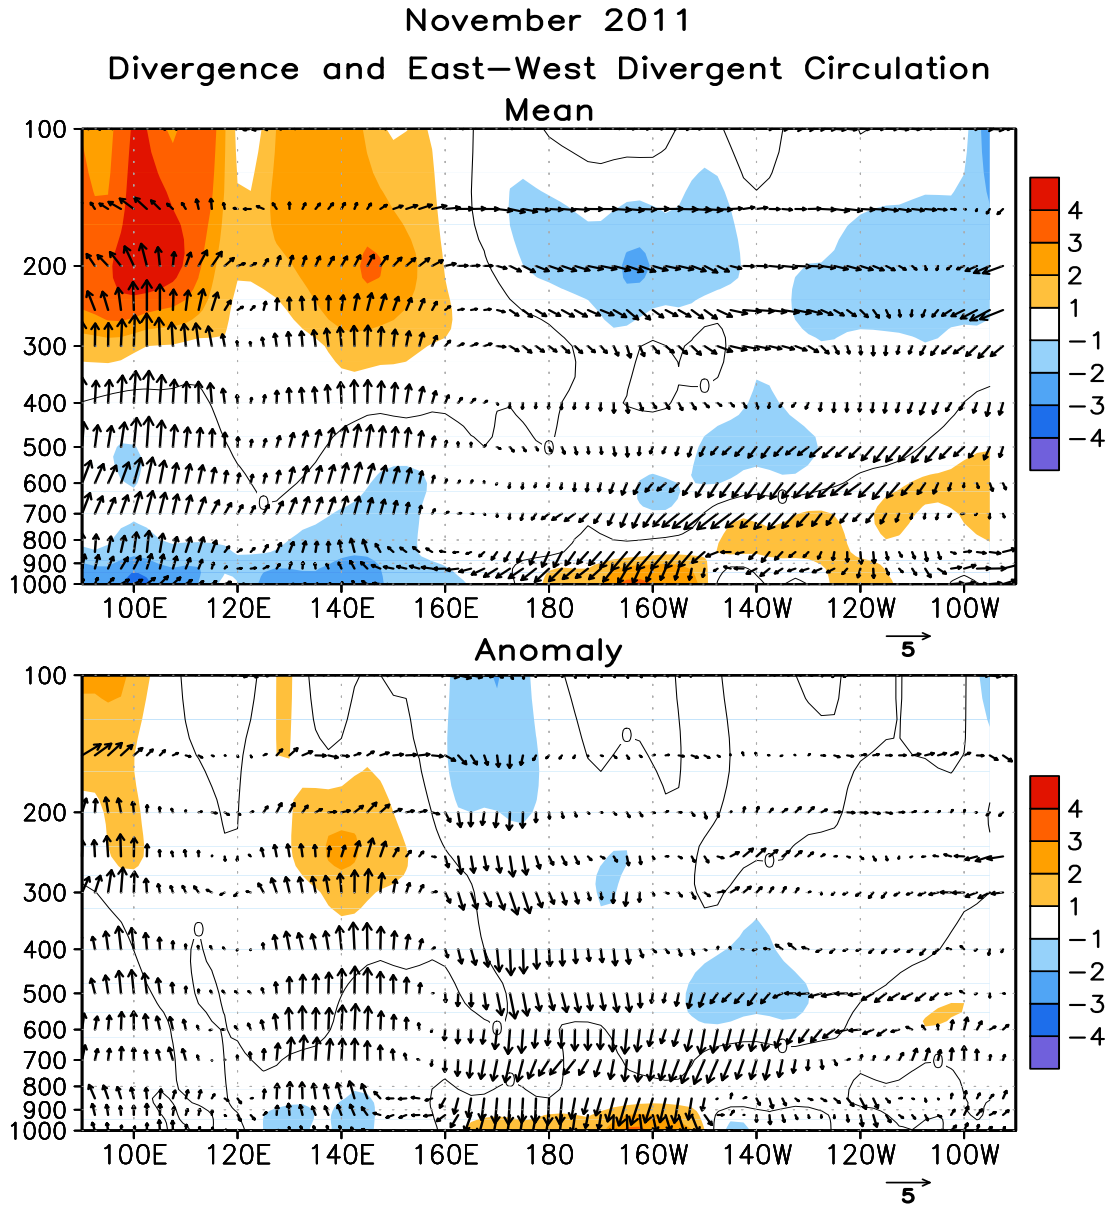

FIGURE T29. Pressure-longitude section (100E-80W) of the mean (top) and anomalous (bottom) divergence (contour interval is  $1 \times 10^{-6} \text{ s}^{-1}$ ) and divergent circulation averaged between 5N-5S. The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the zonal wind. Red shading and solid contours denote divergence (top) and anomalous divergence (bottom). Blue shading and dashed contours denote convergence (top) and anomalous convergence (bottom). Anomalies are departures from the 1981-2010 base period monthly means.

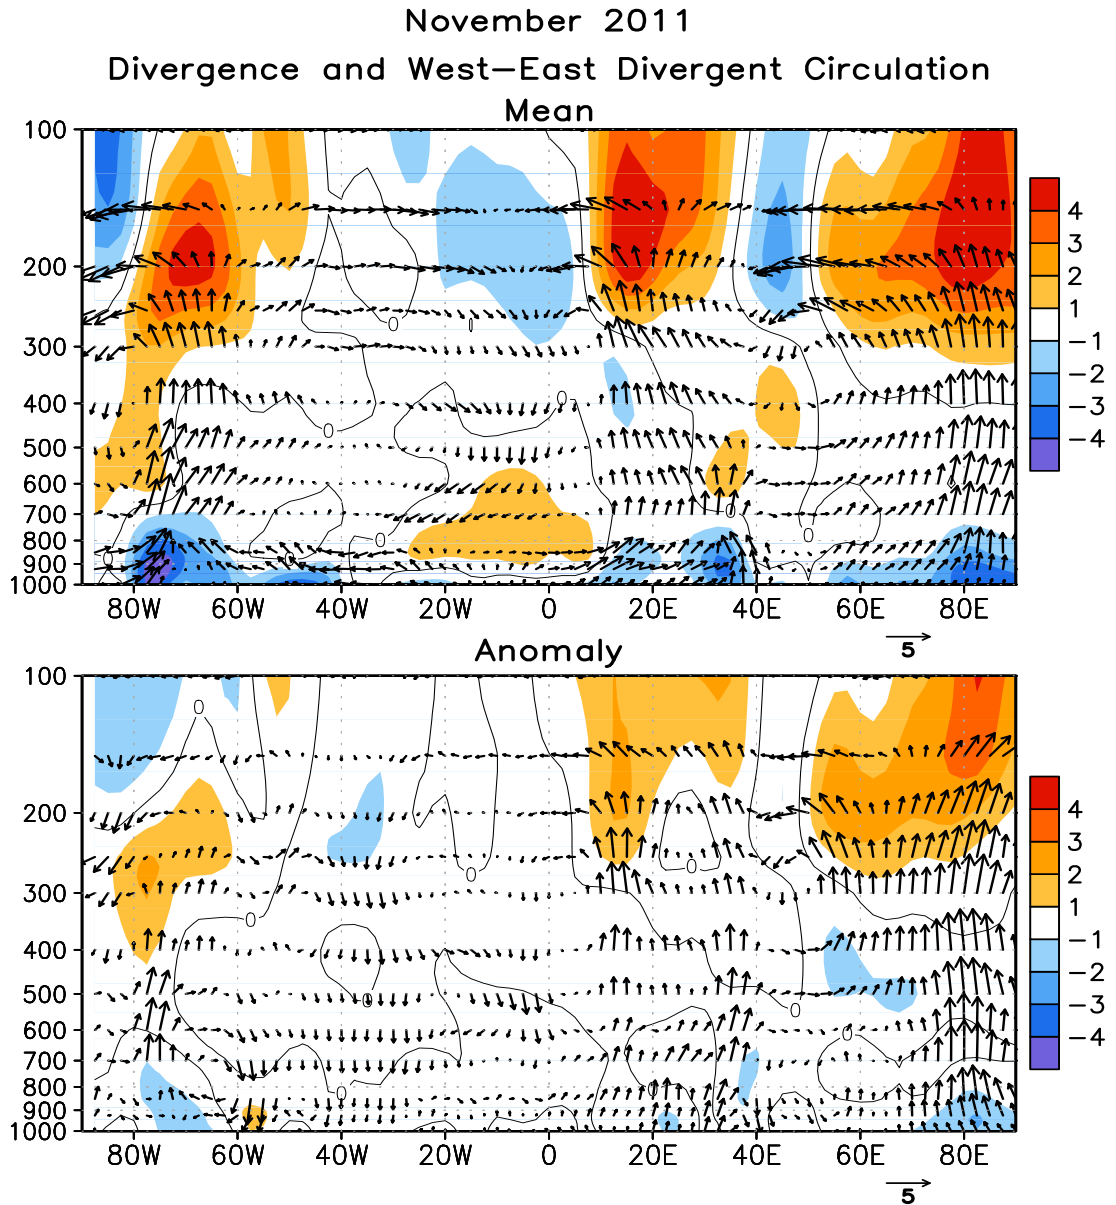

FIGURE T30. Pressure-longitude section (80W-100E) of the mean (top) and anomalous (bottom) divergence (contour interval is  $1 \times 10^{-6} \text{ s}^{-1}$ ) and divergent circulation averaged between 5N-5S. The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the zonal wind. Red shading and solid contours denote divergence (top) and anomalous divergence (bottom). Blue shading and dashed contours denote convergence (top) and anomalous convergence (bottom). Anomalies are departures from the 1981-2010 base period monthly means.

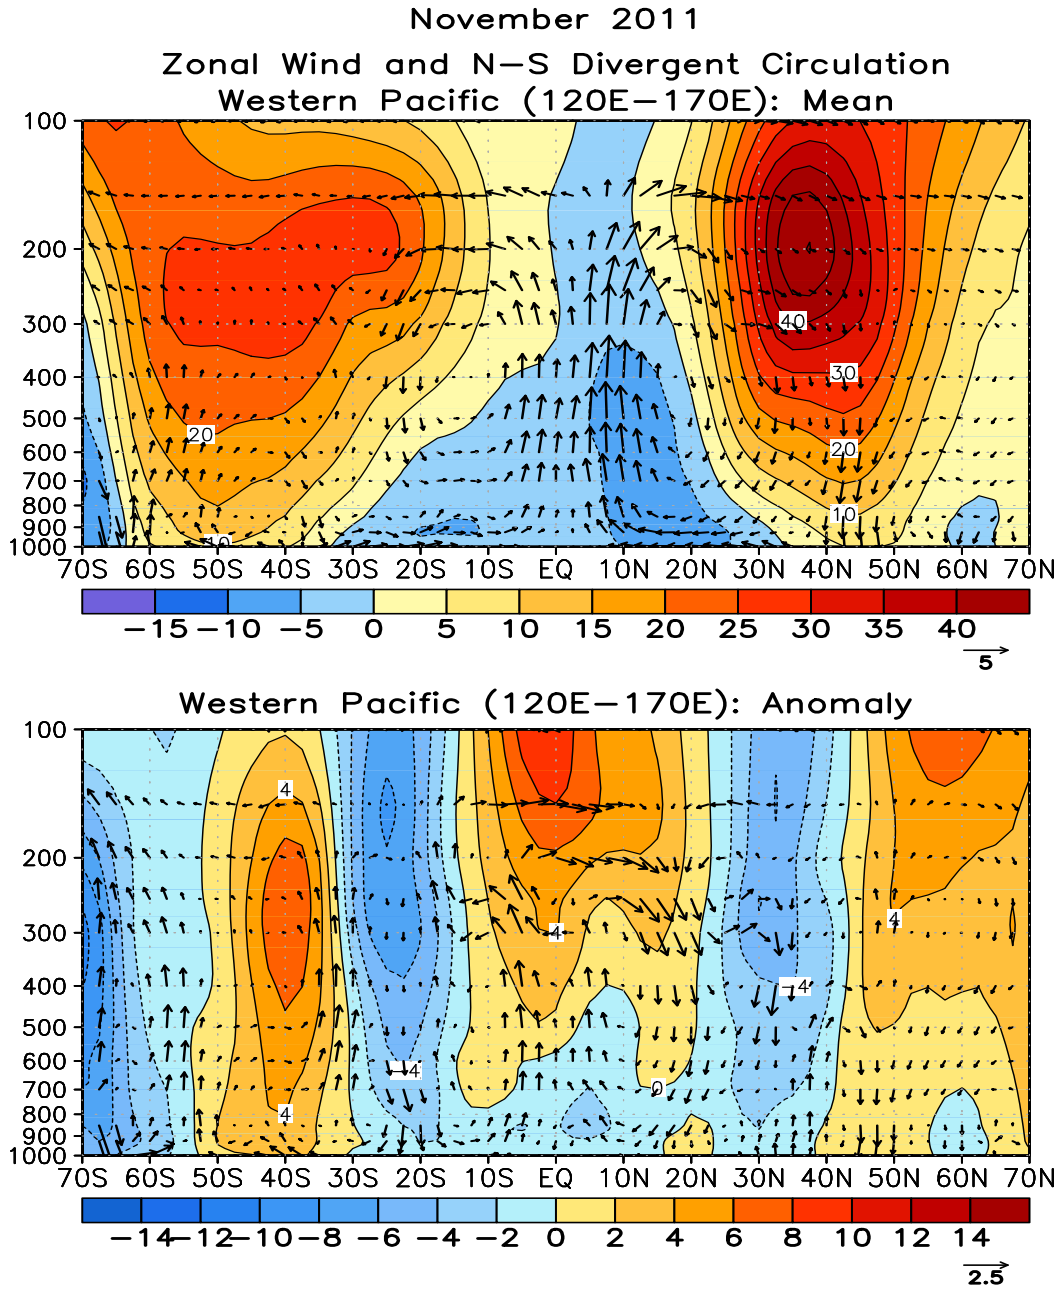

FIGURE T31. Pressure-latitude section of the mean (top) and anomalous (bottom) zonal wind ( $\text{m s}^{-1}$ ) and divergent circulation averaged over the west Pacific sector (120E–170E). The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the meridional wind. Red shading and solid contours denote a westerly (top) or anomalous westerly (bottom) zonal wind. Blue shading and dashed contours denote an easterly (top) or anomalous easterly (bottom) zonal wind. Anomalies are departures from the 1981–2010 base period monthly means.

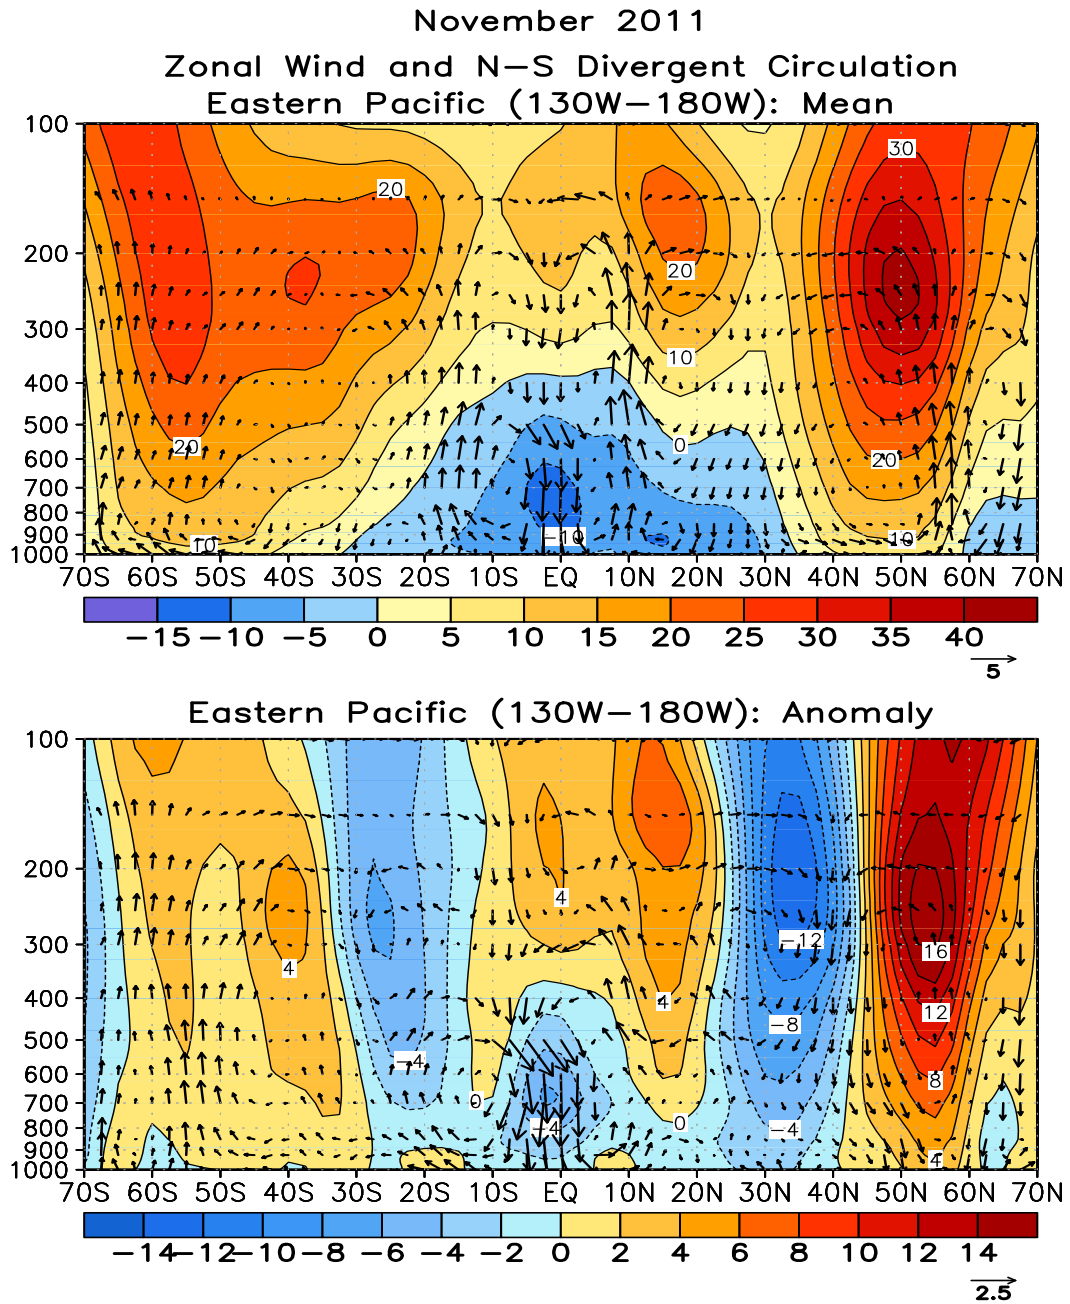

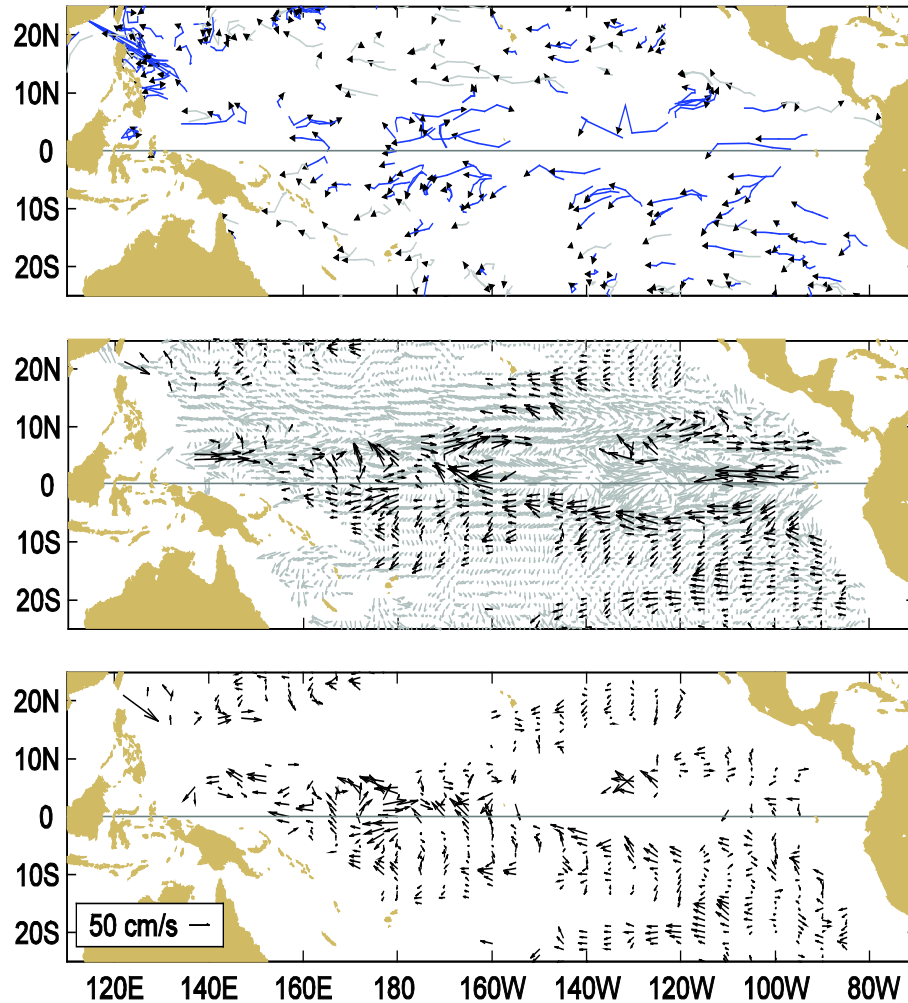

FIGURE T32. Pressure-latitude section of the mean (top) and anomalous (bottom) zonal wind ( $\text{m s}^{-1}$ ) and divergent circulation averaged over the central Pacific sector (130W-180W). The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the meridional wind. Red shading and solid contours denote a westerly (top) or anomalous westerly (bottom) zonal wind. Blue shading and dashed contours denote an easterly (top) or anomalous easterly (bottom) zonal wind. Anomalies are departures from the 1981-2010 base period monthly means.

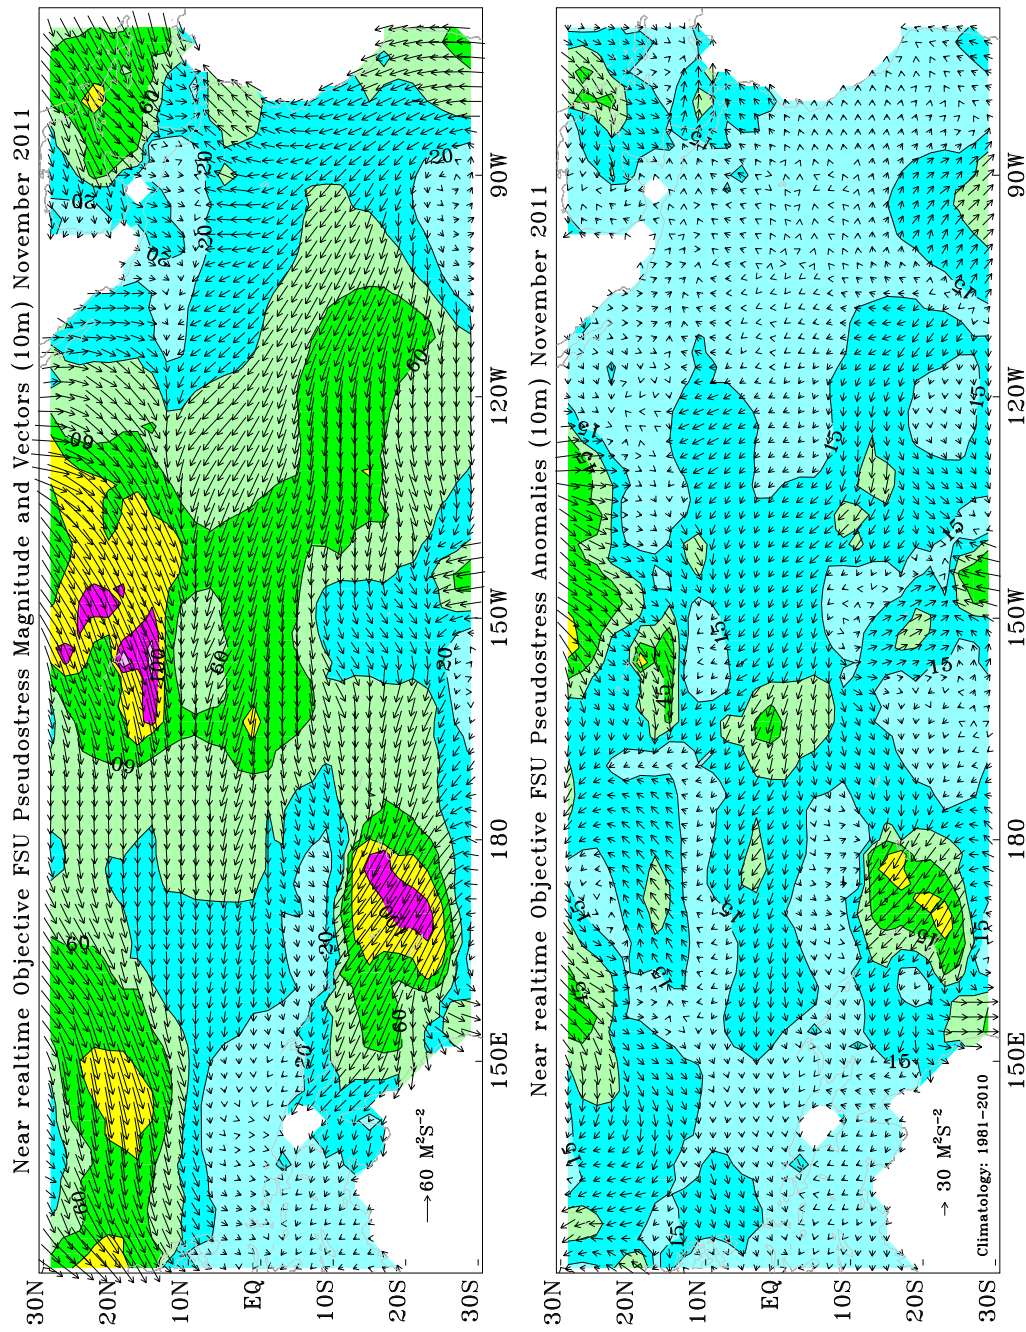

During November 2011, 331 satellite-tracked surface drifting buoys, 56% with subsurface drogues attached for measuring mixed layer currents, were reporting from the tropical Pacific. Across the basin, drifters in the South Equatorial Current measured westward anomalies of  $O(20 \text{ cm/s})$  at 15-20S. Four drifters immediately north of the equator measured strong westward anomalies between 180-160W, but the robustness of this is difficult to determine from drifters alone due to the small sample size. Elsewhere, currents were near their climatological November values. Many drifters north of 10N and west of 160W measured SSTs warmer than normal by 0.5-3.0C, while drifters to the south and east measured SSTs at or slightly cooler ( $0-1.5\text{C}$ ) than climatological November values.

**Figure A1.1 Top:** Movements of drifting buoys in the tropical Pacific Ocean during April 2005. The linear segments of each trajectory represent a one week displacement. Trajectories of buoys which have lost their subsurface drogues are gray; those with drogues are black.

**Middle:** Monthly mean currents calculated from all buoys 1993-2002 (gray), and currents measured by the drogued buoys this month (black) smoothed by an optimal filter.

**Bottom:** Anomalies from the climatological monthly mean currents for this month.

FSU SURFACE PSEUDO-STRESS VECTORS AND ANOMALIES: November 2011. Pseudo-stress vectors (top) are objectively analyzed from ship and buoy winds on a 2° grid. Ship and buoy data are independently weighted and the background field is created from the data. Contour interval of the vector magnitudes is 20  $M^2S^{-2}$ . Anomalies (bottom) are departures from 1981-2010 mean. The contour interval is 15  $M^2S^{-2}$ . For more information, please visit our web site at <http://www.coaps.fsu.edu/RVSMDC/html/winds.shtml>. ## Forecast Forum

The canonical correlation analysis (CCA) forecast of SST in the central Pacific (Barnett et al. 1988, *Science*, **241**, 192196; Barnston and Ropelewski 1992, *J. Climate*, **5**, 13161345), is shown in **Figs. F1 and F2**. This forecast is produced routinely by the Prediction Branch of the Climate Prediction Center. The predictions from the National Centers for Environmental Prediction (NCEP) Coupled Forecast System Model (CFS03) are presented in **Figs. F3 and F4a, F4b**. Predictions from the Markov model (Xue, et al. 2000: *J. Climate*, **13**, 849871) are shown in **Figs. F5 and F6**. Predictions from the latest version of the LDEO model (Chen et al. 2000: *Geophys. Res. Let.*, **27**, 25852587) are shown in **Figs. F7 and F8**. Predictions using linear inverse modeling (Penland and Magorian 1993: *J. Climate*, **6**, 10671076) are shown in **Figs. F9 and F10**. Predictions from the Scripps / Max Planck Institute (MPI) hybrid coupled model (Barnett et al. 1993: *J. Climate*, **6**, 15451566) are shown in **Fig. F11**. Predictions from the ENSOCLIPER statistical model (Knaff and Landsea 1997, *Wea. Forecasting*, **12**, 633652) are shown in **Fig. F12**. Niño 3.4 predictions are summarized in **Fig. F13**, provided by the Forecasting and Prediction Research Group of the IRI.

The CPC and the contributors to the **Forecast Forum** caution potential users of this predictive information that they can expect only modest skill.

## ENSO Alert System Status: [La Niña Advisory](#)

## Outlook

La Niña is expected to continue through the Northern Hemisphere winter 2011-12.

## Discussion

During November 2011, below-average sea surface temperatures (SST) associated with La Niña conditions continued across the eastern and central equatorial Pacific Ocean (**Fig. T18**). The monthly SST indices in the Niño-3.4 and Niño-3 regions were near  $-1.0^{\circ}\text{C}$  (**Table T2**), indicative of weak to moderate La Niña. The oceanic heat content (average temperature in the upper 300m of the ocean) weakened slightly, but still indicates a large area of below-average temperatures at depth in the eastern Pacific (**Fig. T17**). Also reflecting La Niña, the atmospheric circulation over the global tropics featured anomalous low-level easterly and upper-level westerly winds in the central and west-central Pacific (**Figs. T20, T21**). Averaged over the month, convection was suppressed near and just west of the Date Line and enhanced over northern Australia and parts of Indonesia (**Fig. T25**). Collectively, these oceanic and atmospheric patterns are consistent with the continuation of La Niña conditions.

A majority of the models predict a weak or moderate strength La Niña to continue through the Northern Hemisphere winter (**Figs. F1-F13**) and then gradually weaken after peaking during the December – January period. The models are roughly split between those that predict La Niña to remain weak (3-month average in the Niño-3.4 region between  $-0.5$  and  $-0.9^{\circ}\text{C}$ ) and those that predict a stronger episode. Over the last half-century, La Niña events that were preceded by ENSO-neutral conditions during the Northern Hemisphere summer (May-August) were less likely to attain strong amplitude (stronger than  $-1.5^{\circ}\text{C}$ ) the following winter. This observation, in combination with the model forecasts, favors a weak-to-moderate strength La Niña during the Northern Hemisphere winter, likely weakening with the onset of northern spring.

Weekly updates of oceanic and atmospheric conditions are available on the Climate Prediction Center homepage ([El Niño/La Niña Current Conditions and Expert Discussions](#)).

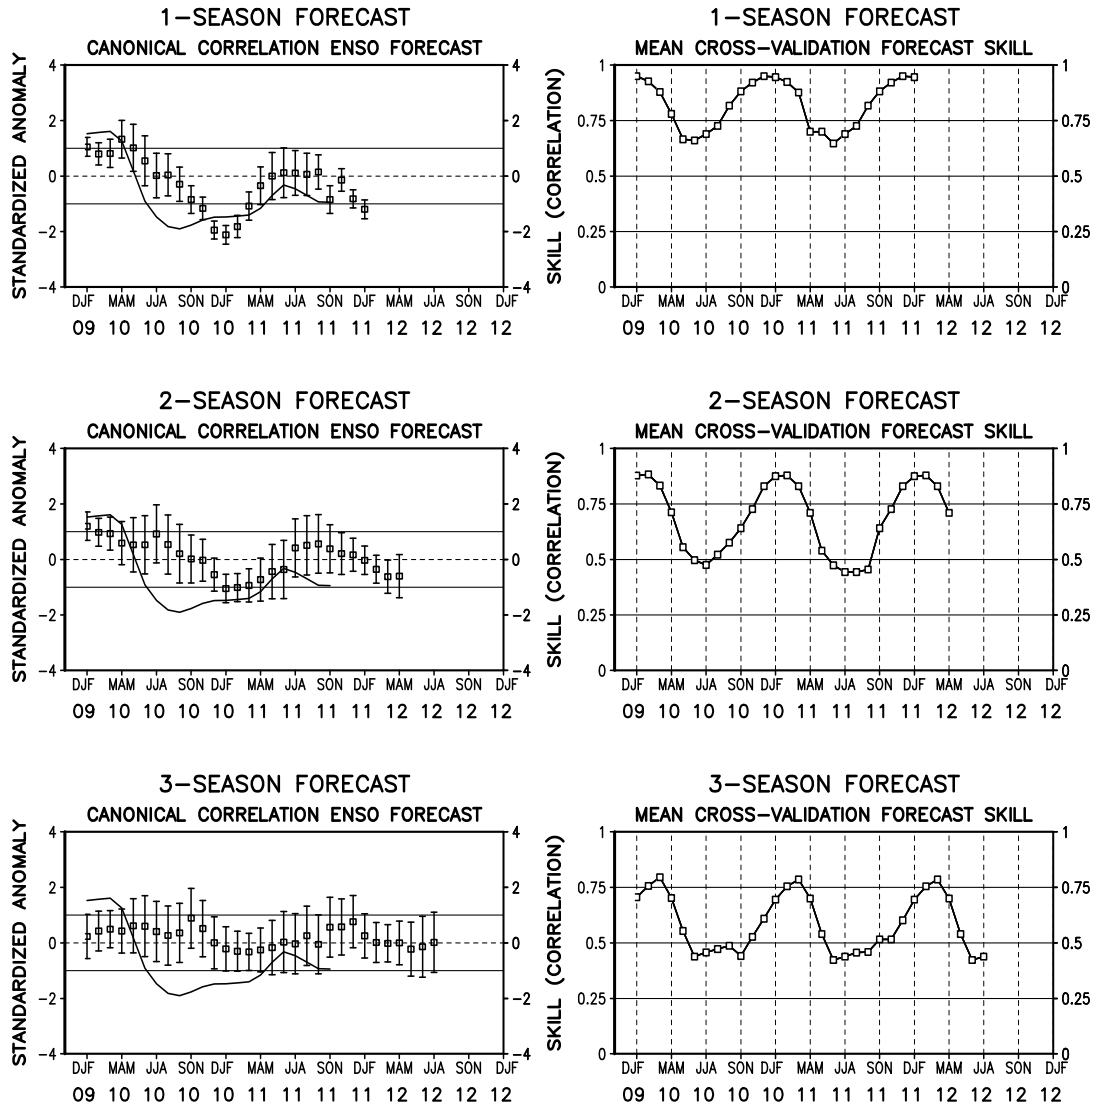

FIGURE F1. Canonical correlation analysis (CCA) sea surface temperature (SST) anomaly prediction for the central Pacific ( $5^{\circ}\text{N}$  to  $5^{\circ}\text{S}$ ,  $120^{\circ}\text{W}$  to  $170^{\circ}\text{W}$  (Barnston and Ropelewski, 1992, *J. Climate*, **5**, 1316-1345). The three plots on the left hand side are, from top to bottom, the 1-season, 2-season, and 3-season lead forecasts. The solid line in each forecast represents the observed SST standardized anomaly through the latest month. The small squares at the mid-points of the forecast bars represent the real-time CCA predictions based on the anomalies of quasi-global sea level pressure and on the anomalies of tropical Pacific SST, depth of the  $20^{\circ}\text{C}$  isotherm and sea level height over the prior four seasons. The vertical lines represent the one standard deviation error bars for the predictions based on past performance. The three plots on the right side are skills, corresponding to the predicted and observed SST. The skills are derived from cross-correlation tests from 1956 to present. These skills show a clear annual cycle and are inversely proportional to the length of the error bars depicted in the forecast time series.

0-4 SEASON LEAD FORECAST  
CANONICAL CORRELATION ENSO FORECAST

FIGURE F2. Canonical Correlation Analysis (CCA) forecasts of sea-surface temperature anomalies for the Niño 3.4 region (5N-5S, 120W-170W) for the upcoming five consecutive 3-month periods. Forecasts are expressed as standardized SST anomalies. The CCA predictions are based on anomaly patterns of SST, depth of the 20C isotherm, sea level height, and sea level pressure. Small squares at the midpoints of the vertical forecast bars represent the CCA predictions, and the bars show the one (thick) and two (thin) standard deviation errors. The solid continuous line represents the observed standardized three-month mean SST anomaly in the Niño 3.4 region up to the most recently available data.

Last update: Wed Nov 2 2011  
Initial conditions: 230ct2011-01Nov2011

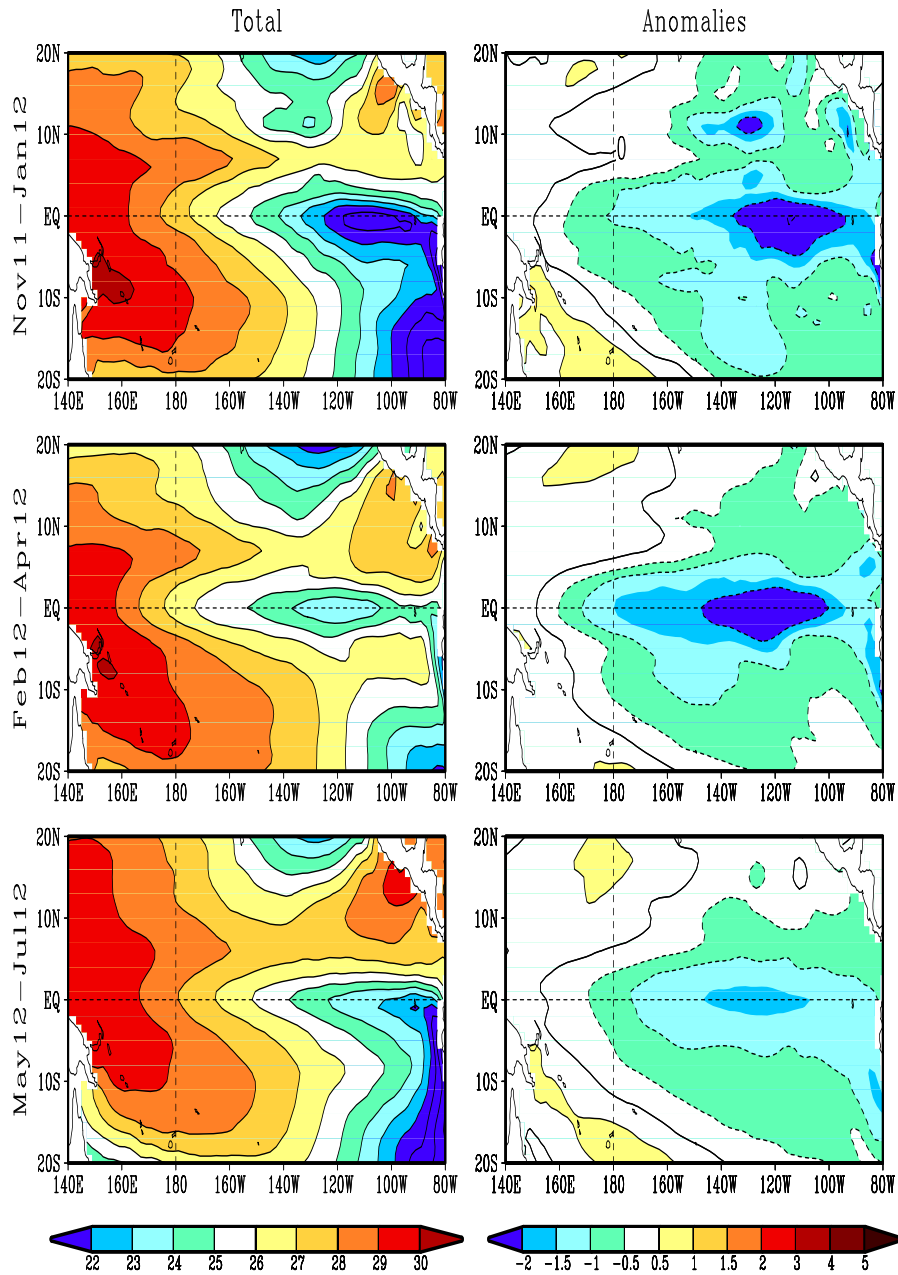

FIGURE F3. Predicted 3-month average sea surface temperature (left) and anomalies (right) from the NCEP Coupled Forecast System Model (CFS03). The forecasts consist of 40 forecast members. Contour interval is 1°C, with additional contours for 0.5°C and -0.5°C. Negative anomalies are indicated by dashed contours.

FIGURE F4. Predicted and observed sea surface temperature (SST) anomalies for the Nino 3 (top) and Nino 3.4 (bottom) regions from the NCEP Coupled Forecast System Model (CFS03). The forecasts consist of 40 forecast members. The ensemble mean of all 40 forecast members is shown by the blue line, individual members are shown by thin lines, and the observation is indicated by the black line. The Nino-3 region spans the eastern equatorial Pacific between 5N-5S, 150W-90W. The Nino 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W.

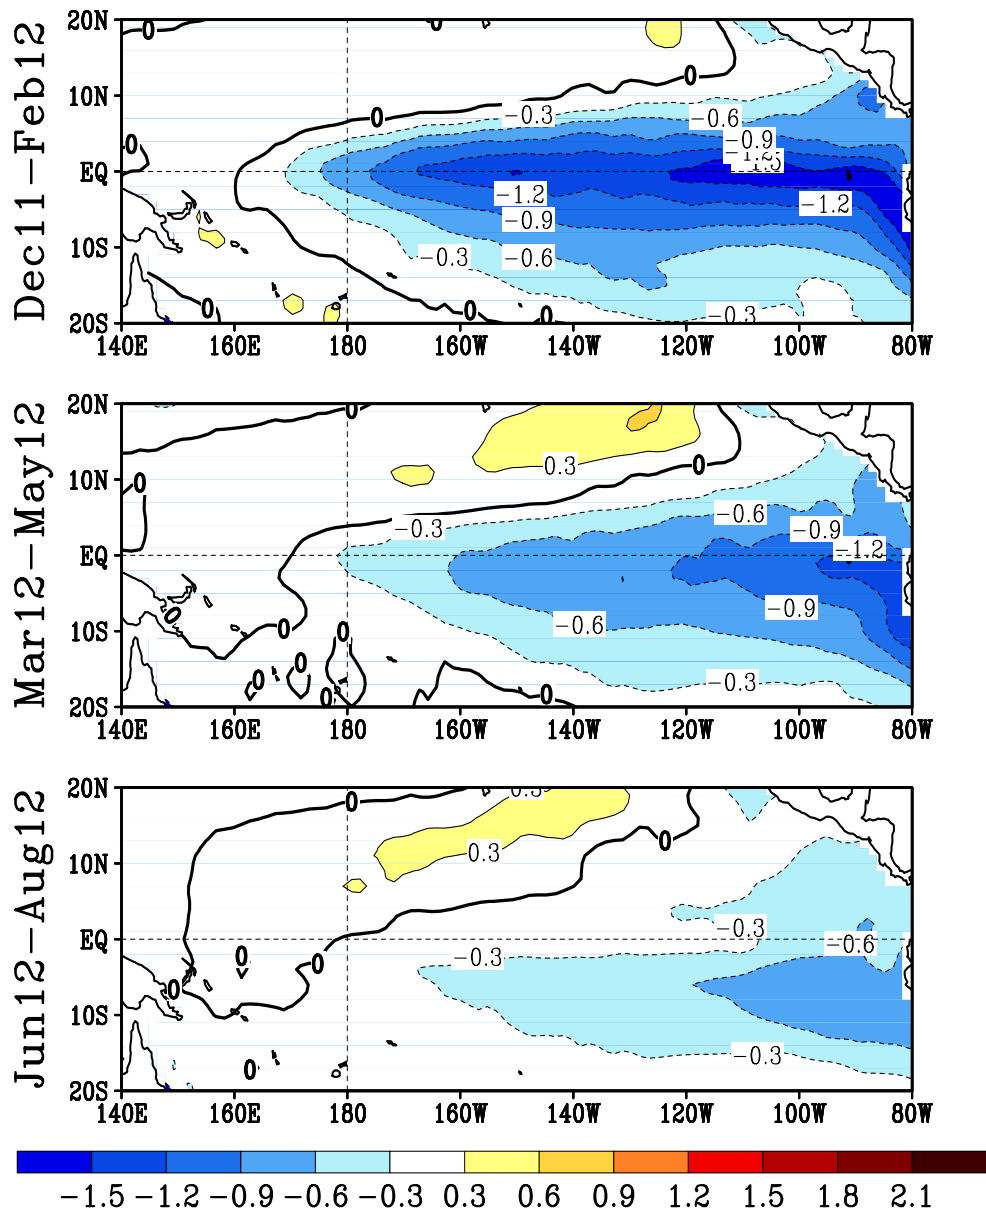

FIGURE F5. Predicted 3-month average sea surface temperature anomalies from the NCEP/CPC Markov model (Xue et al. 2000, *J. Climate*, **13**, 849-871). The forecast is initiated in NOV 2011 . Contour interval is 0.3C and negative anomalies are indicated by dashed contours. Anomalies are calculated relative to the 1971-2000 climatology.

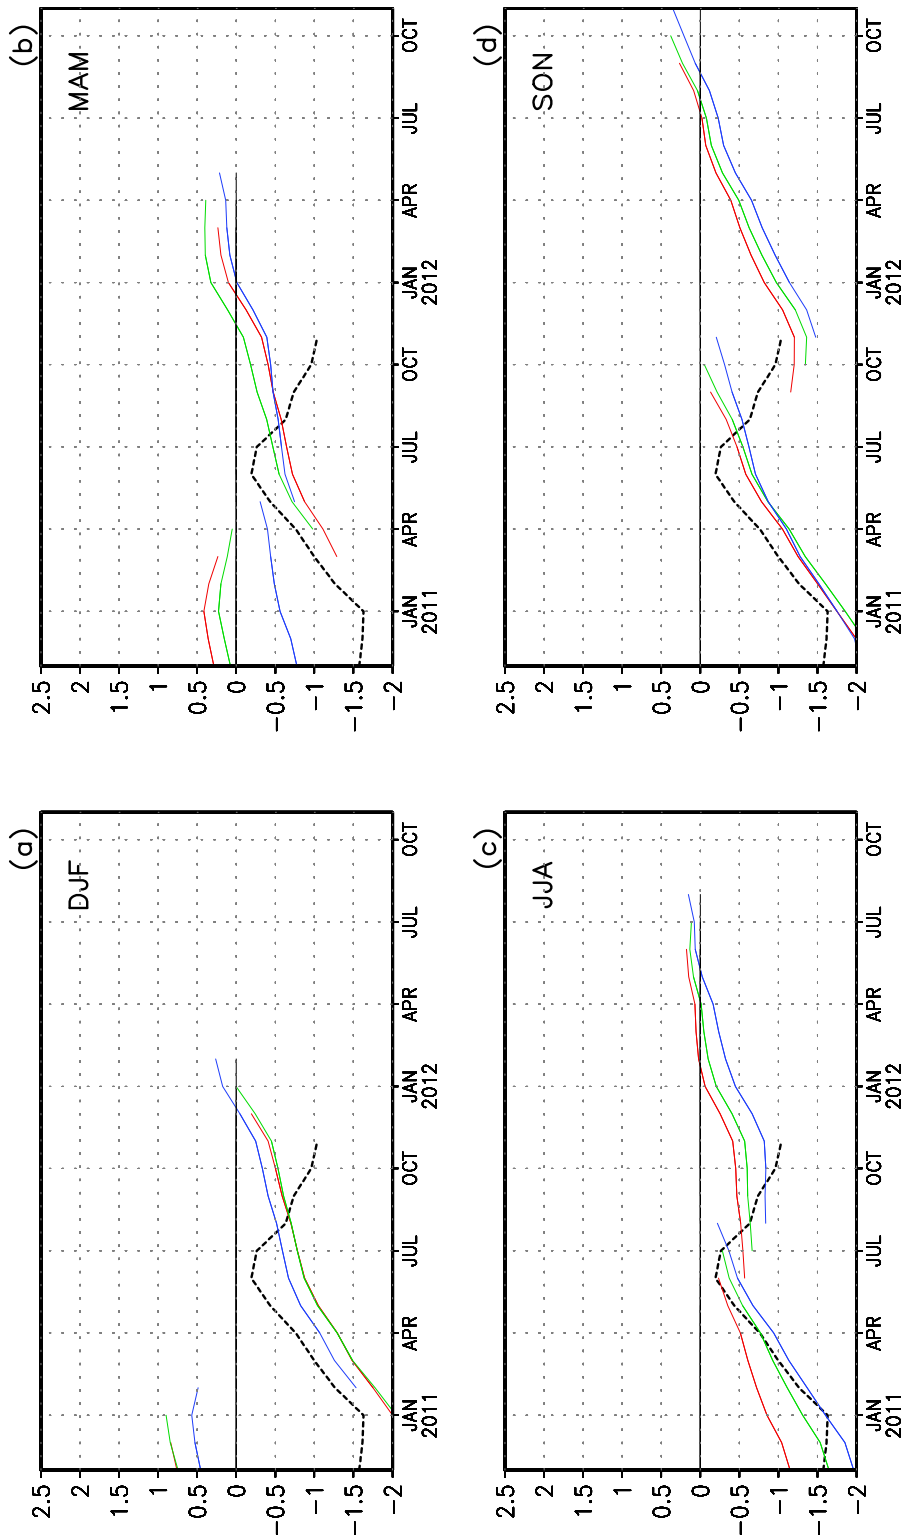

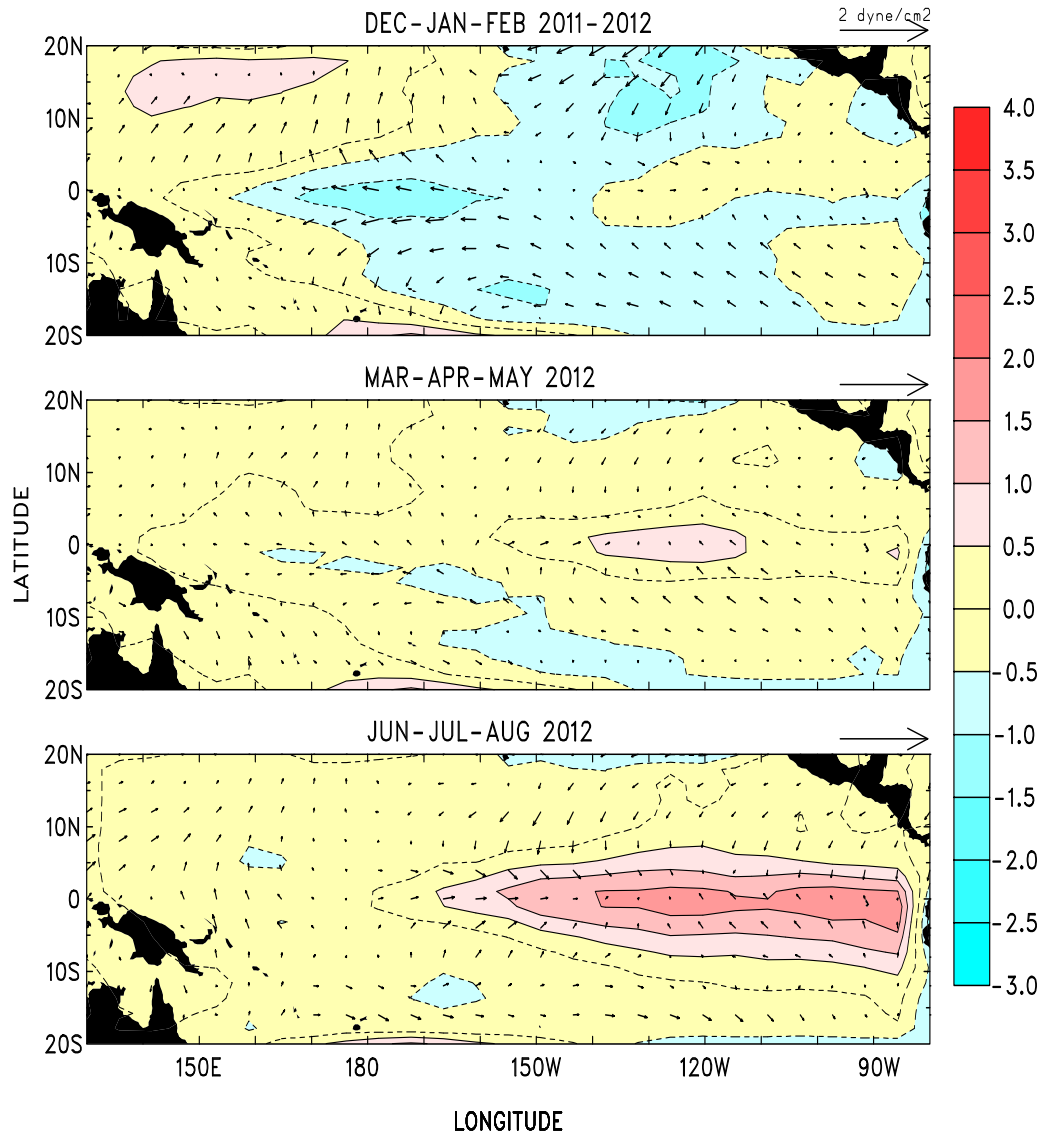

FIGURE F6. Time evolution of observed and predicted SST anomalies in the Niño 3.4 region (up to 12 lead months) by the NCEP/CPC Markov model (Xue et al. 2000, *J. Climate*, **13**, 849-871). Anomalies are calculated relative to the 1971-2000 climatology. Shown in each panel are the forecasts grouped by three consecutive starting months: (a) is for December, January, and February, (b) is for March, April, and May, (c) is for June, July, and August, and (d) is for September, October, and November. The observed Niño 3.4 SST anomalies are indicated by the black dashed lines. The Niño 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W.

# LDEO FORECASTS OF SST AND WIND STRESS ANOMALIES

**FIGURE F7.** Forecasts of the tropical Pacific Predicted SST (shading) and vector wind anomalies for the next 3 seasons based on the LDEO model. Each forecast represents an ensemble average of 3 sets of predictions initialized during the last three consecutive months (see Figure F8).

### LDEO FORECASTS OF NINO3

**FIGURE F8.** LDEO forecasts of SST anomalies for the Niño 3 region using wind stresses obtained from (top) QuikSCAT, (middle) NCEP, and (bottom) Florida State Univ. (FSU), along with SSTs (obtained from NCEP), and sea surface height data (obtained from TOPEX/POSEIDON) data. Each thin blue line represents a 12-month forecast, initialized one month apart for the past 24 months. Observed SST anomalies are indicated by the thick red line. The Niño-3 region spans the eastern equatorial Pacific between 5N-5S, 150W-90W.

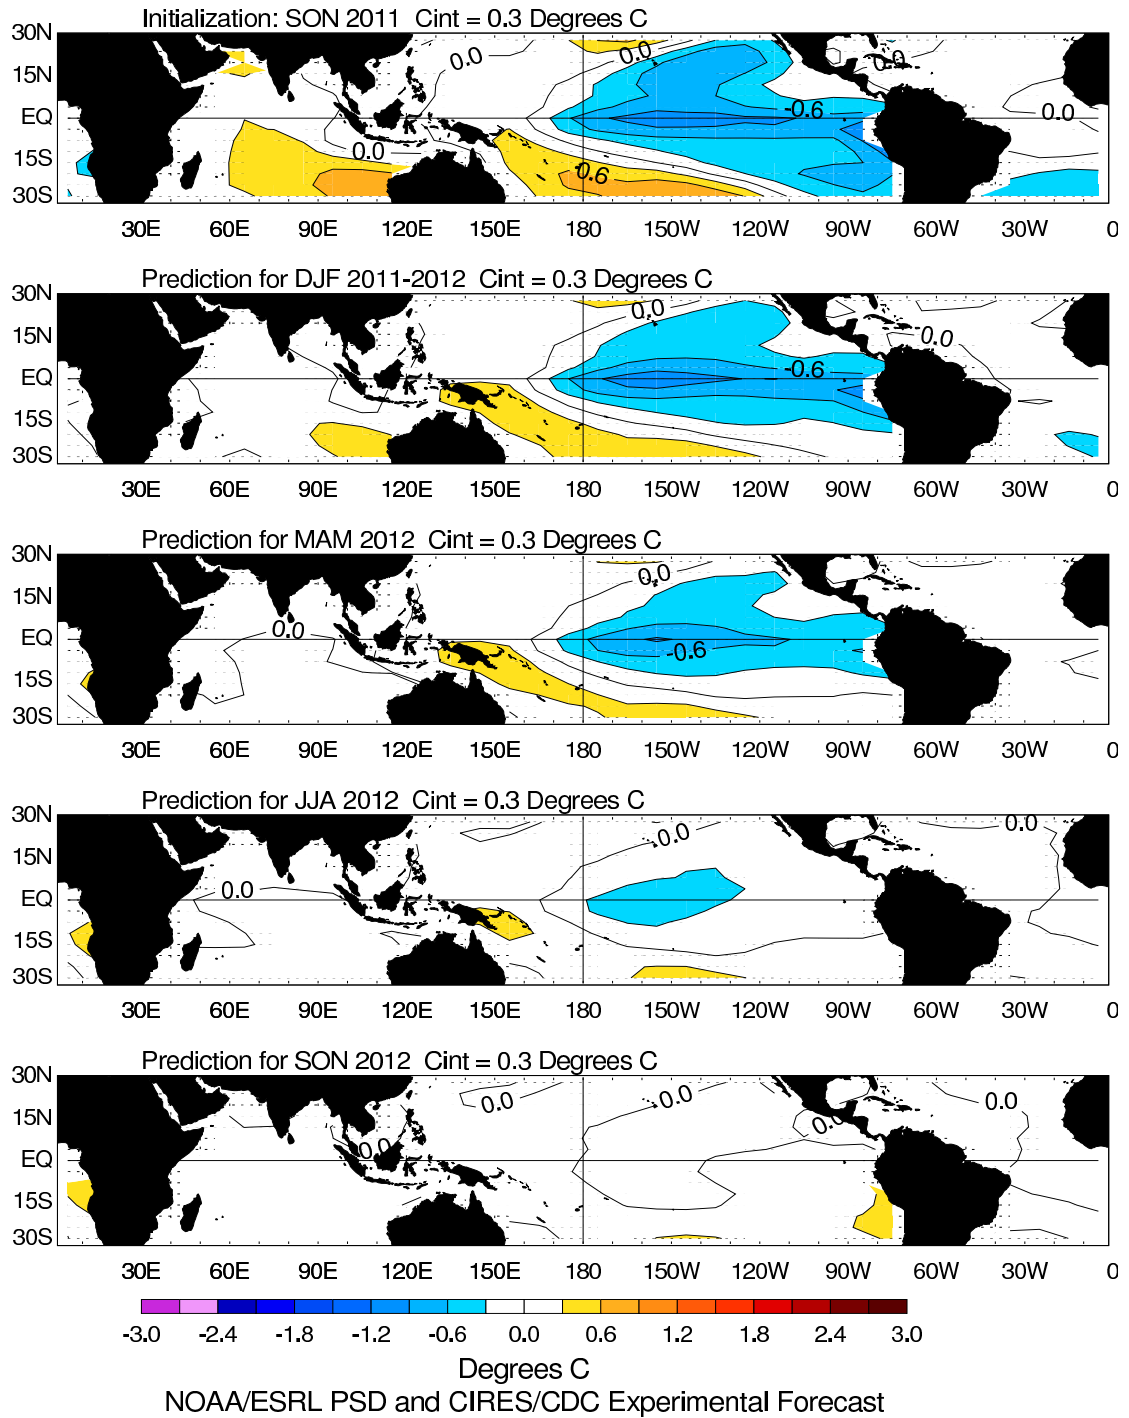

FIGURE F9. Forecast of tropical SST anomalies from the Linear Inverse Modeling technique of Penland and Magorian (1993: *J. Climate*, **6**, 1067-1076). The contour interval is 0.3C. Anomalies are calculated relative to the 1981-2010 climatology and are projected onto 20 leading EOFs.

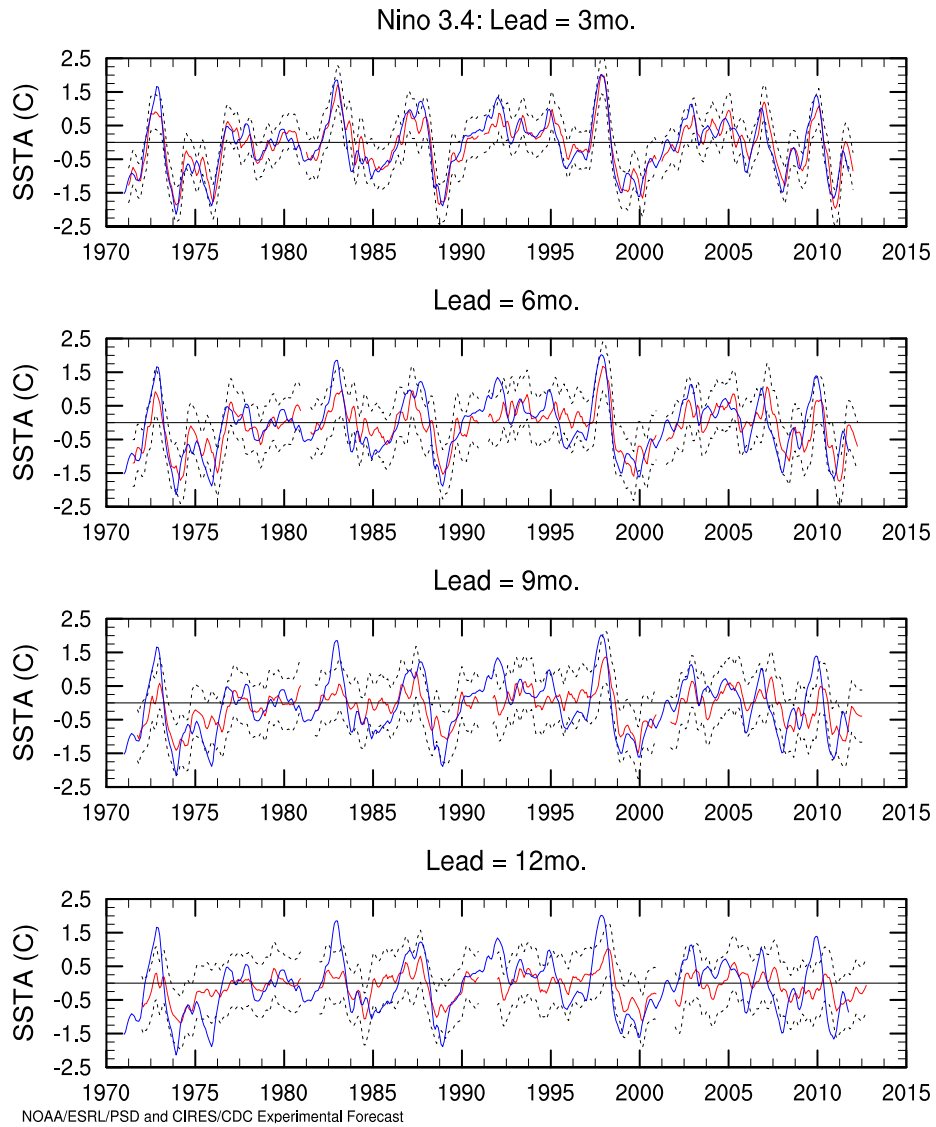

FIGURE F10. Predictions of Niño 3.4 SSTA (blue solid line) and verification (solid red line). The Niño3.4 Index was calculated in the area 6N-6S, 170W-120W. The 1980-2010 climatology was subtracted from ERSST data between 1950 and 2010, after which they were projected onto 20 EOFs containing 90% of the variance. Significant 1950-2010 trends were subtracted from the corresponding PCs, the forecast was made on the detrended anomalies, after which the trend was added to the forecast. The dotted lines indicate the one standard deviation confidence interval for the forecasts based on a perfect adherence to assumption.

SIO/MPI HCM-T3.0 Tropical SST Anomaly Forecast, 09 Dec 2011

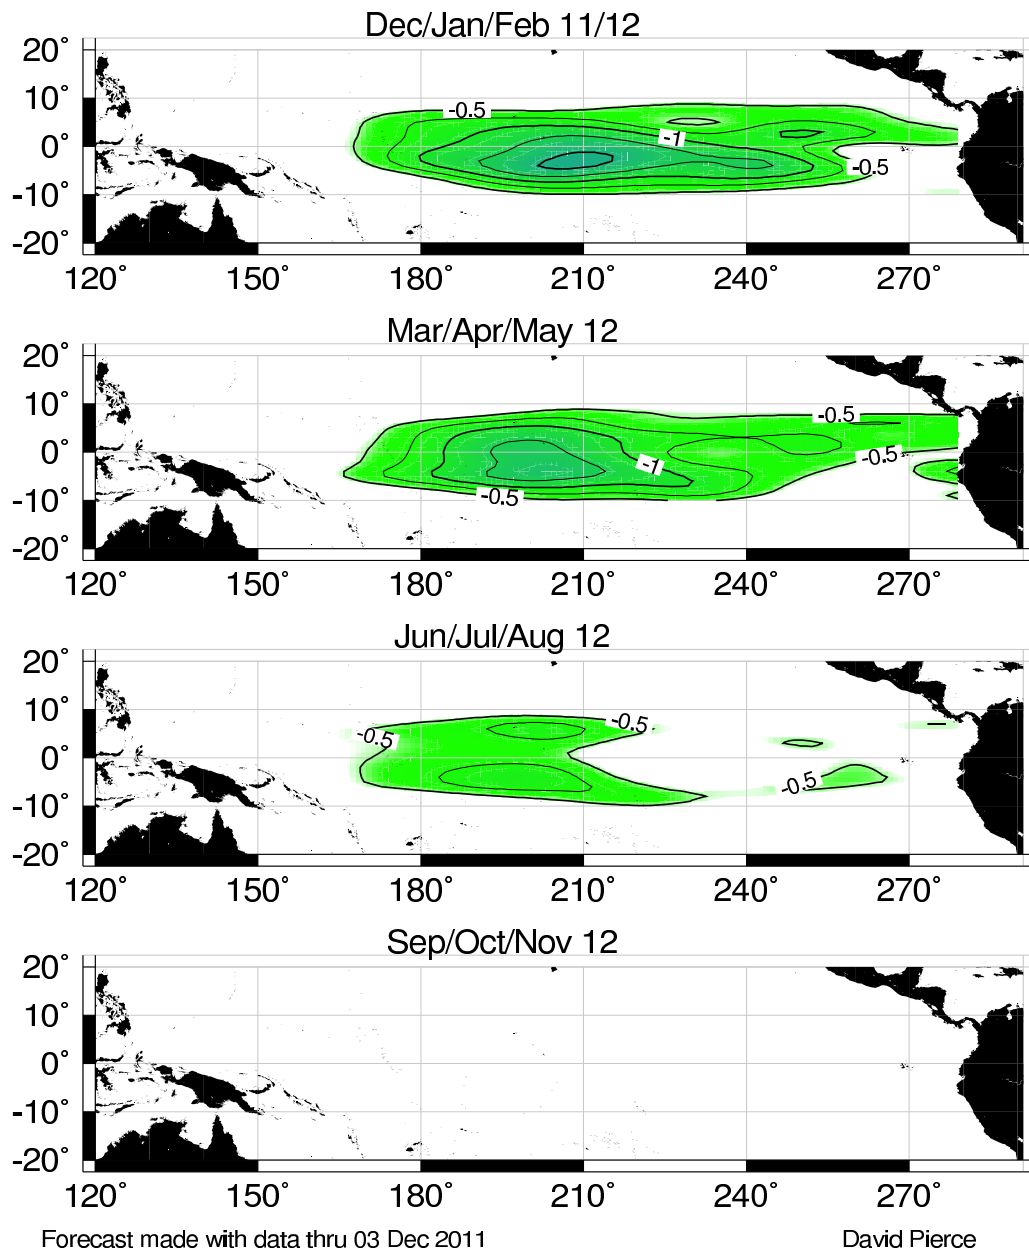

FIGURE F11. SST anomaly forecast for the equatorial Pacific from the Hybrid Coupled Model (HCM) developed by the Scripps Institution of Oceanography and the Max-Planck Institut fuer Meteorologie.

FIGURE F12. ENSO-CLIPER statistical model forecasts of three-month average sea surface temperature anomalies (green lines, deg. C) in (top panel) the Nino 4 region (5N-5S, 160E-150W), (second panel) the Nino 3.4 region (5N-5S, 170W-120W), (third panel) the Nino 3 region (5N-5S, 150W-90W), and (fourth panel) the Nino 1+2 region (0-10S, 90W-80W) (Knaff and Landsea 1997, *Wea. Forecasting*, **12**, 633-652). Bottom panel shows predictions of the three-month standardized Southern Oscillation Index (SOI, green line). Horizontal bars on green line indicate the adjusted root mean square error (RMSE). The Observed three-month average values are indicated by the thick blue line. SST anomalies are departures from the 1981-2010 base period means, and the SOI is calculated from the 1951-1980 base period means.

## Model Predictions of ENSO from Nov 2011

FIGURE F13. Time series of predicted sea surface temperature anomalies for the Nino 3.4 region (deg. C) from various dynamical and statistical models for nine overlapping 3-month periods. The Nino 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W. Figure provided by the International Research Institute (IRI).

# Extratropical Highlights – November 2011

## 1. Northern Hemisphere

The 500-hPa circulation during November featured a persistent zonal wave-4 anomaly pattern (**Fig. E11**), with above average heights over the central North Pacific, eastern Canada, Europe, and eastern Asia (**Fig. E9**). Below average heights were observed over northwestern North America, the central North Atlantic, central Russia, and eastern Siberia. This overall pattern projected onto three prominent teleconnections, including the positive phases of the North Atlantic Oscillation (NAO, +1.3) and East Atlantic/ Western Russia pattern (+2.1), and the negative phase (-1.3) of the East Pacific-North Pacific (EP) pattern (**Table E1, Fig. E7**).

The circulation over the Pacific/ North American sector showed links to La Niña. This link is most evident at 200-hPa, where a 3-celled pattern of extratropical height anomalies spanning the central Pacific to eastern north America is seen to emanate from a large area of cyclonic streamfunction anomalies over the central subtropical Pacific (**Fig. T22**). These cyclonic anomalies reflect an enhanced mid-Pacific trough and a marked westward retraction of the East Asian jet core (**Fig. T21**), both of which are a well-known response to the La Niña- related suppression of tropical convection across the central equatorial Pacific (**Fig. T25**).

The main surface temperature signals during November included warmer-than-average conditions across eastern Canada, central Europe, Scandinavia, and China, and below average temperatures in Alaska and the Middle East (**Fig. E1**). The main precipitation signals included above-average totals in the mid-western U.S., southern Europe, and eastern China, and below-average totals along the U.S. Gulf Coast and much of Europe (**Fig. E3**).

### a. North Pacific and North America

The mean 500-hPa circulation during November featured above average heights over the central North Pacific and eastern North America, and below average heights over Alaska and western Canada (**Fig. E9**). This pattern projected onto the negative phase (-1.3) of the East Pacific-North Pacific (EP) teleconnection pattern (**Table E1, Fig. E7**). When viewed in combination with the cyclonic streamfunction anomalies over the central subtropical North Pacific, this overall pattern can be interpreted as an anomalous wave train emanating from the tropical Pacific in association with La Niña (**Fig. T22**).

La Niña is associated with deep tropical convection focused over Indonesia and the eastern Indian Ocean, along with a disappearance of tropical convection from the central equatorial Pacific (**Fig. T25**). This westward retraction in the area of deep convection acts to amplify the mean mid-Pacific troughs at 200-hPa in both hemispheres (**Fig. T22**), which in the NH results in a westward retraction the east Asian jet stream and its associated jet exit region (**Fig. T21**). This jet structure favors corresponding westward shifts in the downstream ridge and trough axes normally located over western and eastern North America, respectively. During November, for example, these features were located over the central North Pacific and western North America, respectively.

These overall conditions were associated with above average surface temperatures across eastern Canada and below average temperatures in Alaska (**Fig. E1**). Large portions of eastern Canada have recorded positive temperature departures above the 90th percentile of occurrences for the last two months. Also during November, above-average precipitation was recorded in the Tennessee and

Ohio Valleys, along with below-average precipitation along the U.S. Gulf Coast (**Fig. E3**). These precipitation signals are typical of the wintertime response to La Niña.

#### b. North Atlantic and Europe

The 500-hPa circulation during November featured a large-amplitude wave pattern extending from eastern North America to Mongolia (**Fig. E9**). Prominent features of this pattern included a strong ridge over Europe and deep troughs over both the central North Atlantic and western Russia. These anomalies projected onto the positive phases of the North Atlantic Oscillation (NAO, +1.3) and the East Atlantic/ Western Russia pattern (+2.1) (**Table E1, Fig. E7**).

This overall circulation was associated with an enhanced northward transport of mild air into Scandinavia, resulting in surface temperature departures above the 90th percentile of occurrences (**Fig. E1**). It was also associated with an enhanced southward transport of colder air and below average temperatures across southwestern Russia and the Middle East. The mean ridge and trough positions also strongly controlled the precipitation patterns, with above-average totals observed over southern Europe and south-central Russia in the areas downstream of the mean trough axes, and well below-average totals across the remainder of Europe and western Russia in the vicinity of the amplified ridge axis (**Fig. E3**).

## 2. Southern Hemisphere

The 500-hPa circulation during November featured above average heights over Antarctica, eastern Australia, the central South Pacific Ocean, and the central South Atlantic Ocean (**Fig. E15**). It also featured below average heights extending from southern Africa to South America. At 200-hPa the subtropical circulation featured an extensive area of cyclonic streamfunction anomalies across the central South Pacific Ocean in association with La Niña (**Fig. T22**).

In Australia, an east-west dipole pattern of surface temperature anomalies was present during November, with above average temperatures in the east and below average temperatures in the west (**Fig. E1**). These conditions were associated with a broad upper-level trough-ridge couplet, which spanned the continent from west to east. Most of central and eastern Australia also recorded above-average precipitation, with many areas recording totals in the upper 90th percentile of occurrences (**Fig. E3**).

The SH ozone hole was at record high size during the first half of the month (**Fig. S8**, top), covering approximately 15 million square kilometers in mid-November. This size is approximately double the average for the time of the year, and occurred in association with a record large SH polar vortex (**Fig. S8**, middle). The ozone hole then rapidly weakened during the 3rd week of November in response to a sharp reduction in size of the polar vortex. By the end of November, the ozone hole was near the average size of 5 million square kilometers.

Overall, the 2011 ozone hole developed rapidly in mid-August, which is slightly later than its normal onset in early August. It then reached peak extent from mid-September to early October, spanning approximately 24 million square kilometers. The ozone hole remained persistent and large during mid-October through mid-November, with a record areal extent of 20 million square kilometers throughout the period. The rapid decay of the ozone hole in late November reflected the normal late-spring weakening of the polar vortex.

TABLE E1-Standardized amplitudes of selected Northern Hemisphere teleconnection patterns for the most recent thirteen months (computational procedures are described in Fig. E7). Pattern names and abbreviations are North Atlantic Oscillation (NAO); East Atlantic pattern (EA); West Pacific pattern (WP); East Pacific - North Pacific pattern (EP-NP); Pacific/North American pattern (PNA); Tropical/Northern Hemisphere pattern (TNH); East Atlantic/Western Russia pattern (EATL/WRUS)-called Eurasia-2 pattern by Barnston and Livezey, 1987, *Mon. Wea. Rev.*, **115**, 1083-1126); Scandinavia pattern (SCAND-called Eurasia-1 pattern by Barnston and Livezey 1987); and Polar Eurasia pattern (POLEUR). No value is plotted for calendar months in which the pattern does not appear as a leading mode.

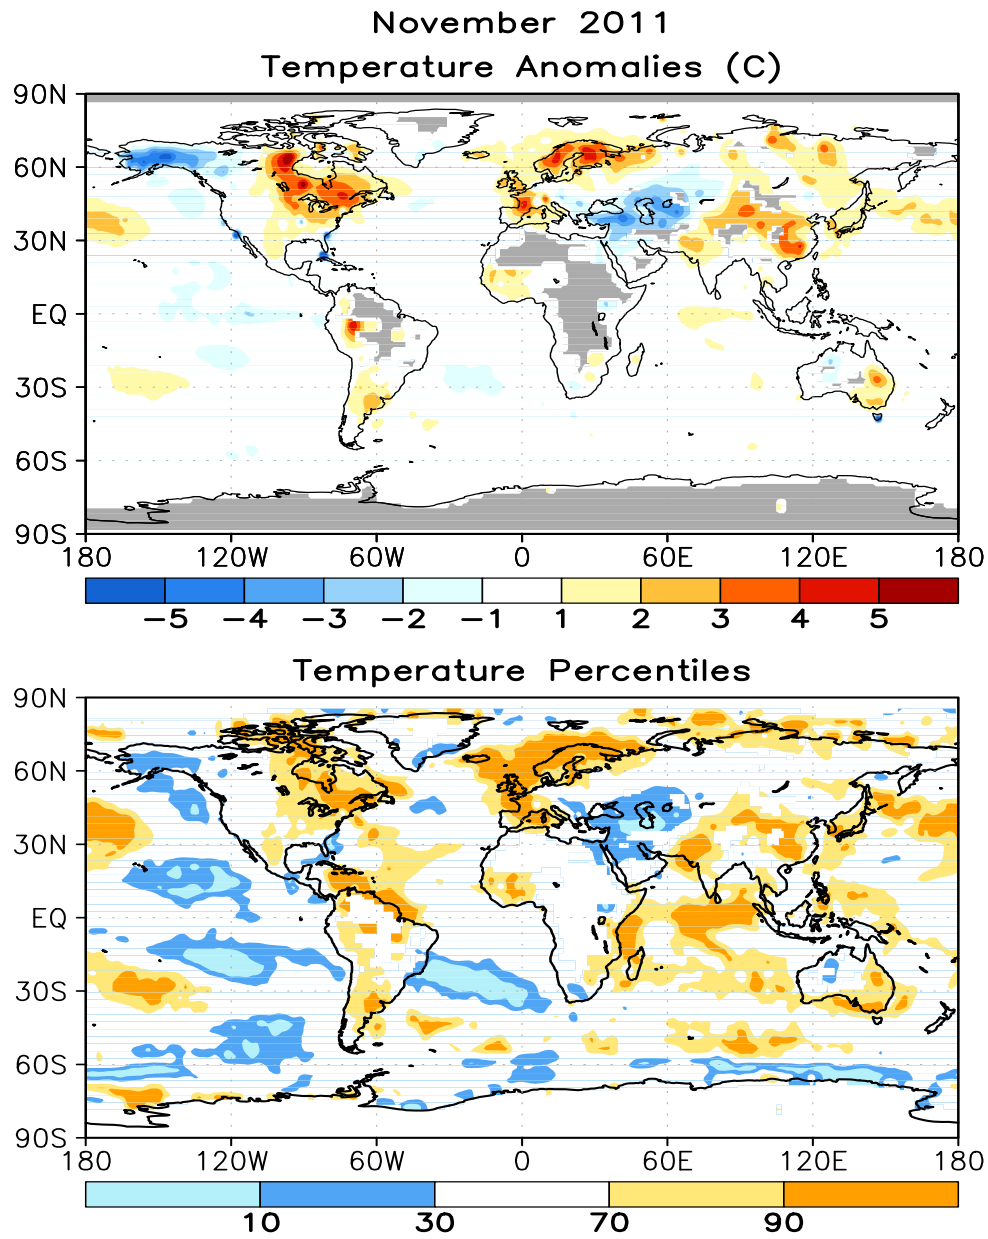

FIGURE E1. Surface temperature anomalies ( $^{\circ}\text{C}$ , top) and surface temperature expressed as percentiles of the normal (Gaussian) distribution fit to the 1981–2010 base period data (bottom) for NOV 2011. Analysis is based on station data over land and on SST data over the oceans (top). Anomalies for station data are departures from the 1981–2010 base period means, while SST anomalies are departures from the 1981–2010 adjusted OI climatology. (Smith and Reynolds 1998, *J. Climate*, **11**, 3320–3323). Regions with insufficient data for analysis in both figures are indicated by shading in the top figure only.

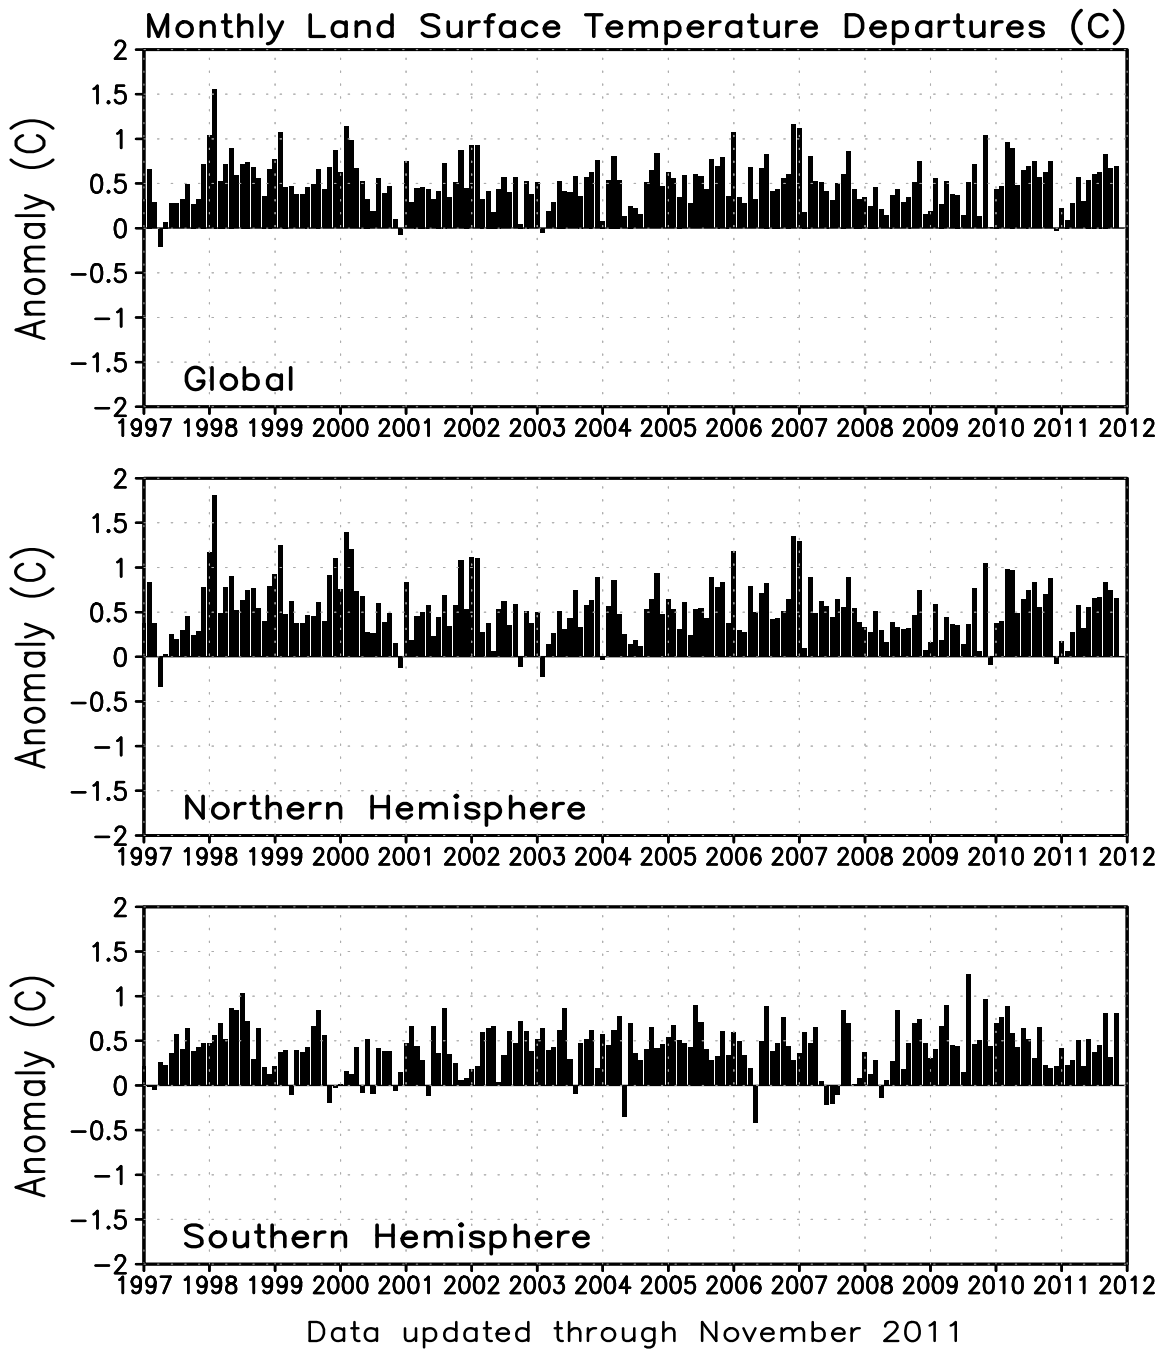

FIGURE E2. Monthly global (top), Northern Hemisphere (middle), and Southern Hemisphere (bottom) surface temperature anomalies (land only, °C) from January 1990 - present, computed as departures from the 1981–2010 base period means.

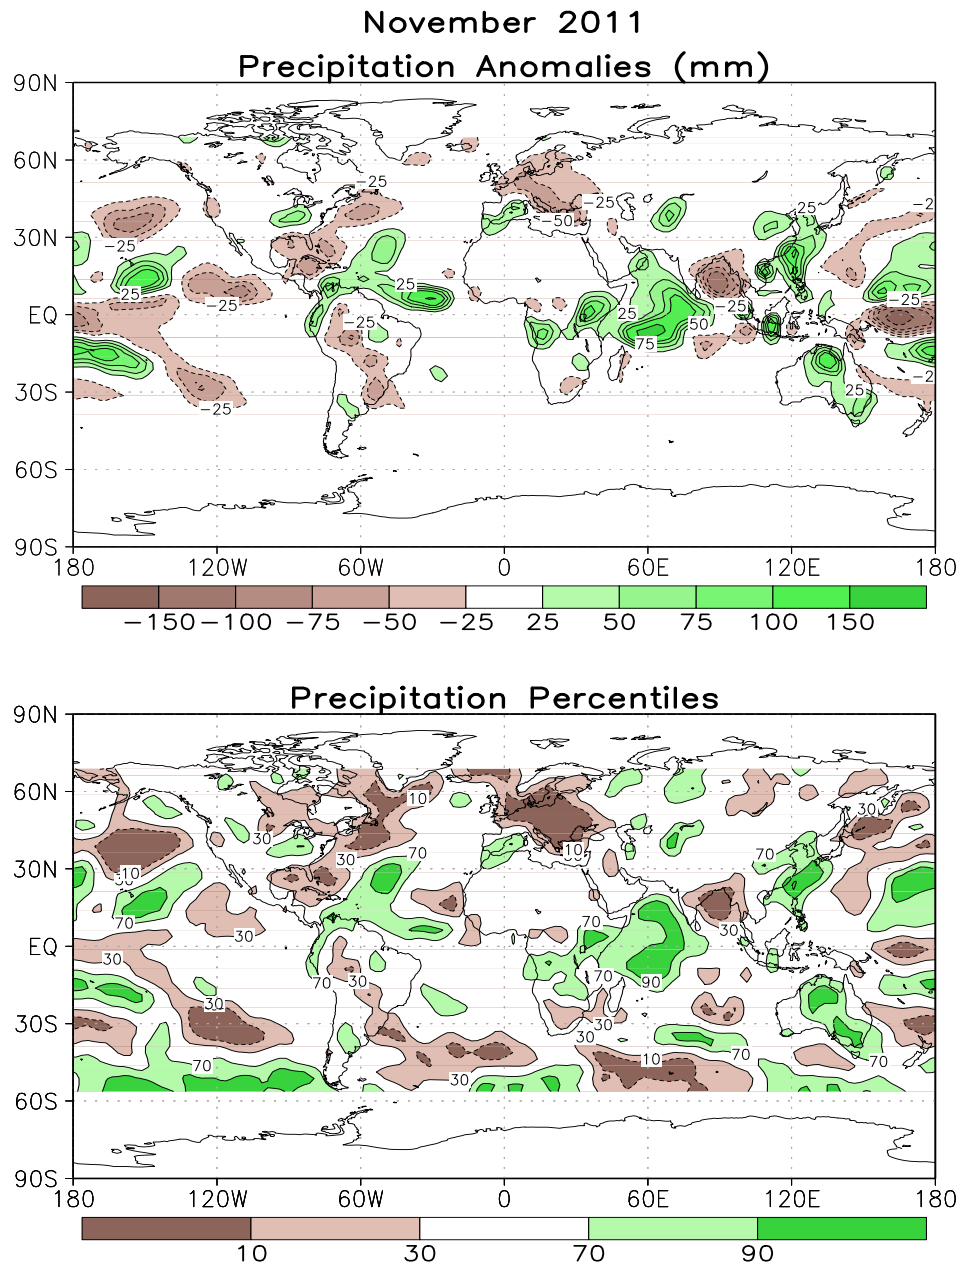

FIGURE E3. Anomalous precipitation (mm, top) and precipitation percentiles based on a Gamma distribution fit to the 1981–2010 base period data (bottom) for NOV 2011. Data are obtained from a merge of raingauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, **12**, 3335–3342). Contours are drawn at 200, 100, 50, 25, -25, -50, -100, and -200 mm in top panel. Percentiles are not plotted in regions where mean monthly precipitation is <5mm/month.

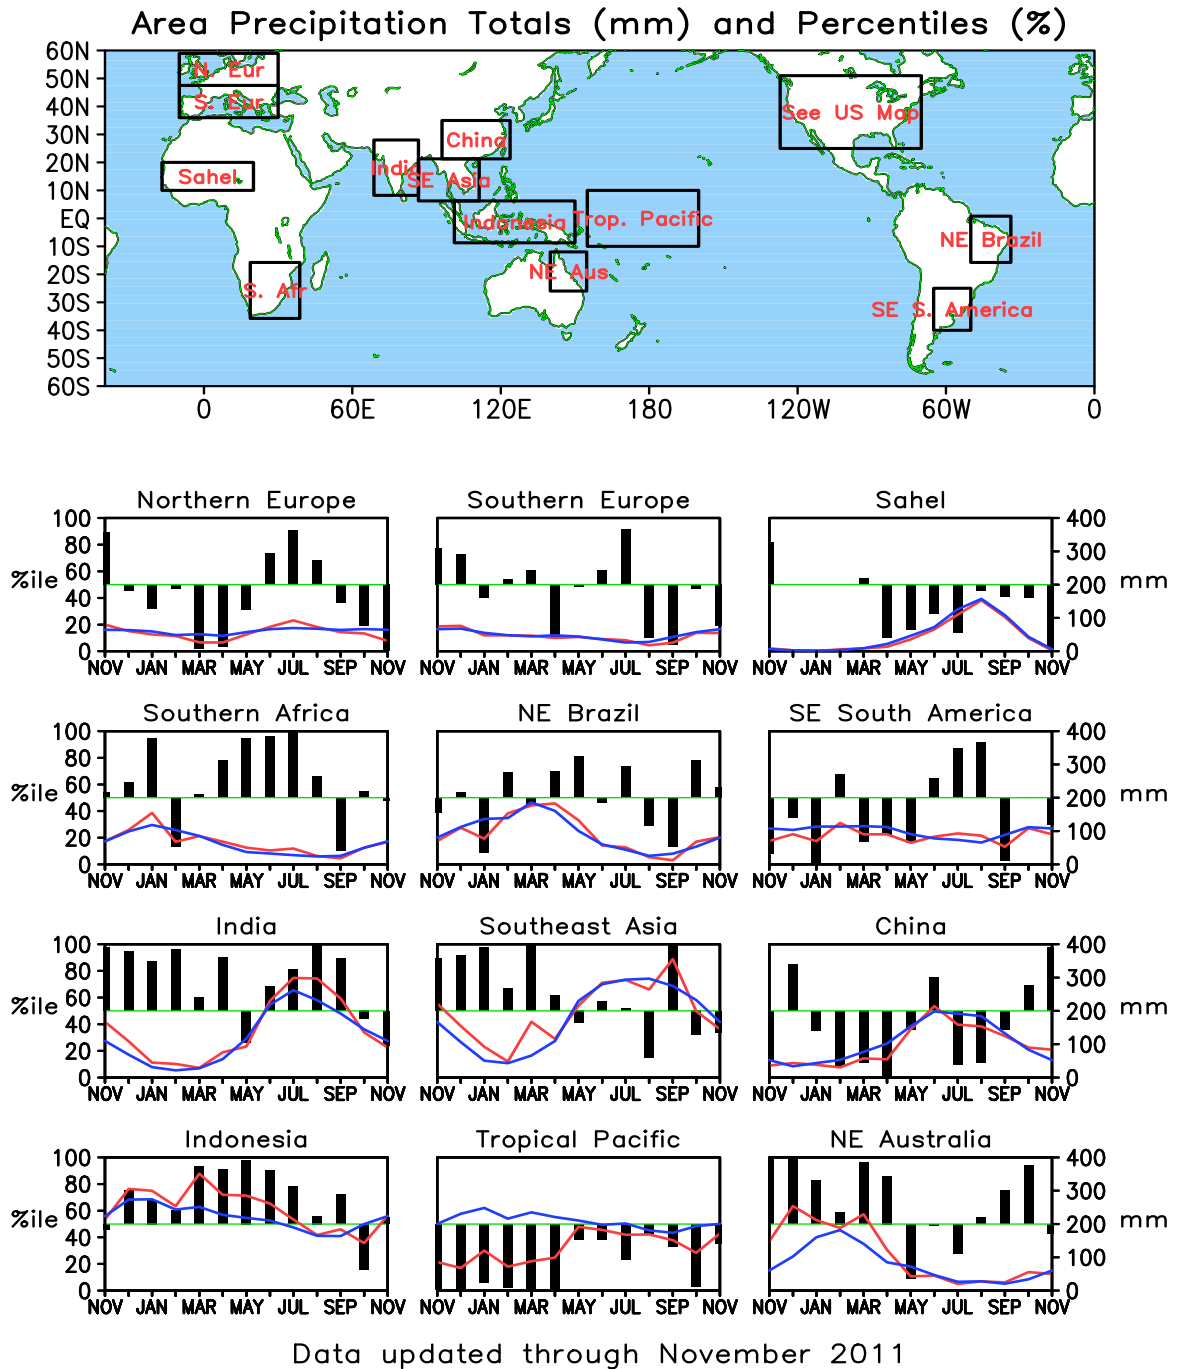

FIGURE E4. Areal estimates of monthly mean precipitation amounts (mm, solid lines) and precipitation percentiles (% , bars) for the most recent 13 months obtained from a merge of rain gauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, 12, 3335–3342). The monthly precipitation climatology (mm, dashed lines) is from the 1981–2010 base period monthly means. Monthly percentiles are not shown if the monthly mean is less than 5 mm.

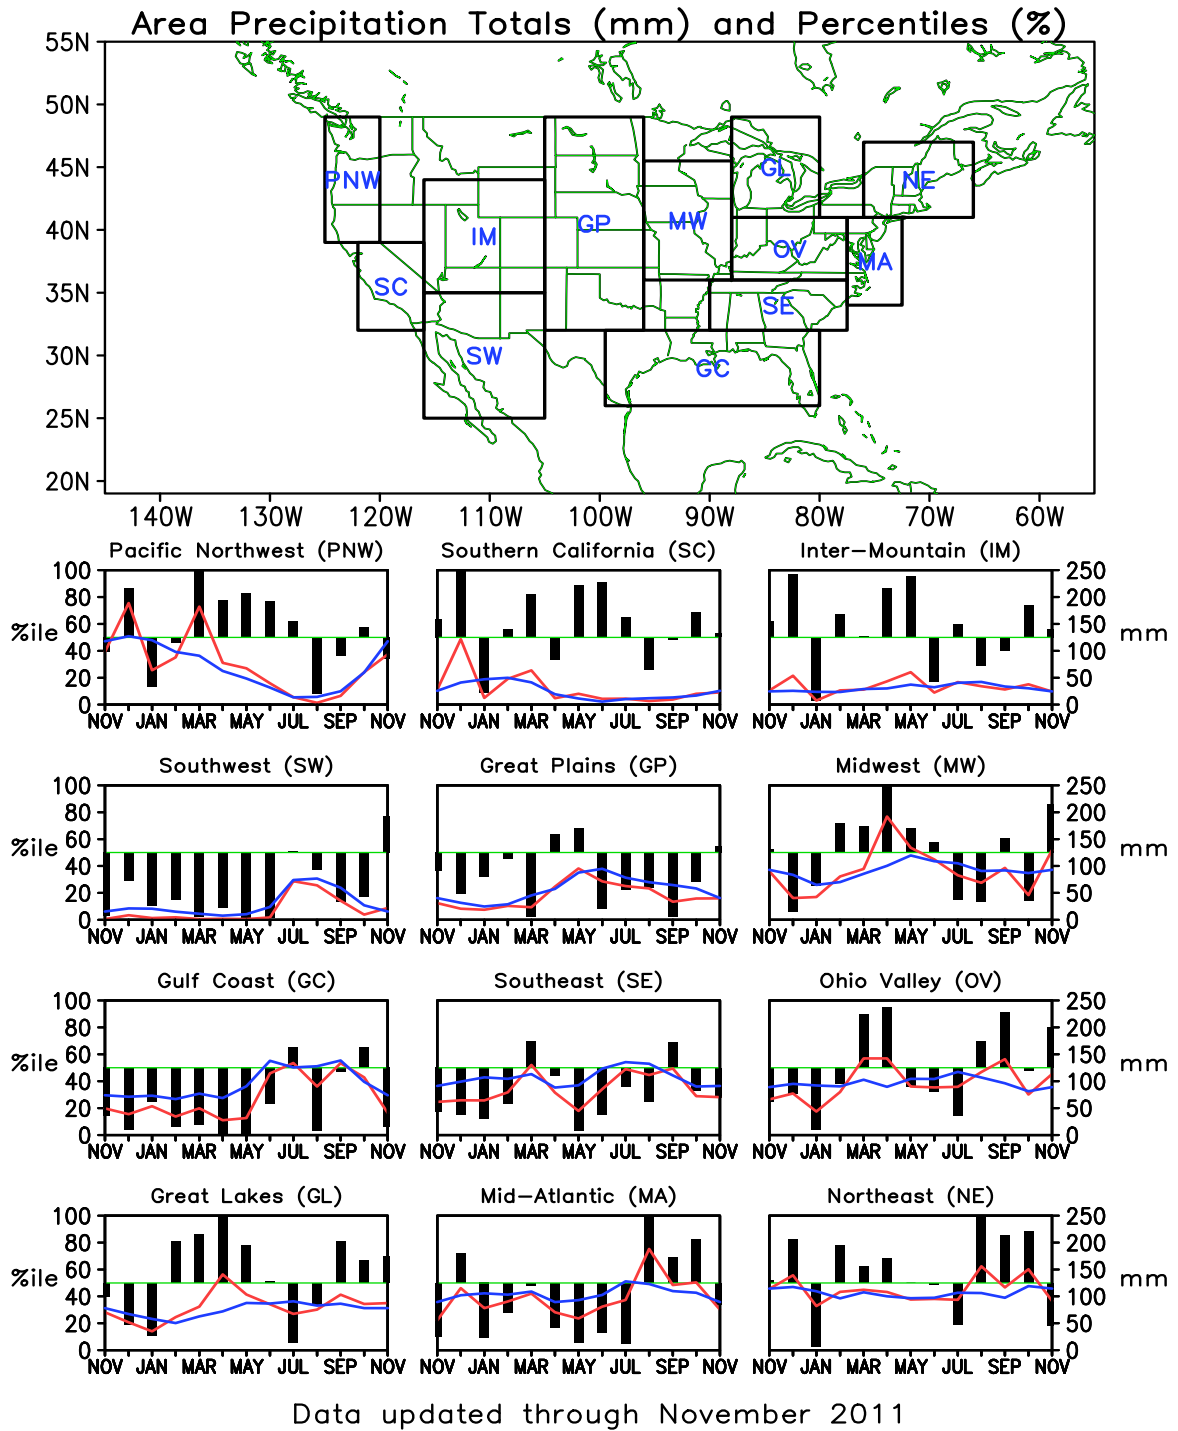

FIGURE E5. Areal estimates of monthly mean precipitation amounts (mm, solid lines) and precipitation percentiles (% , bars) for the most recent 13 months obtained from a merge of raingauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, **12**, 3335–3342). The monthly precipitation climatology (mm, dashed lines) is from the 1981–2010 base period monthly means. Monthly percentiles are not shown if the monthly mean is less than 5 mm.

Monthly Accumulation -- November, 2011

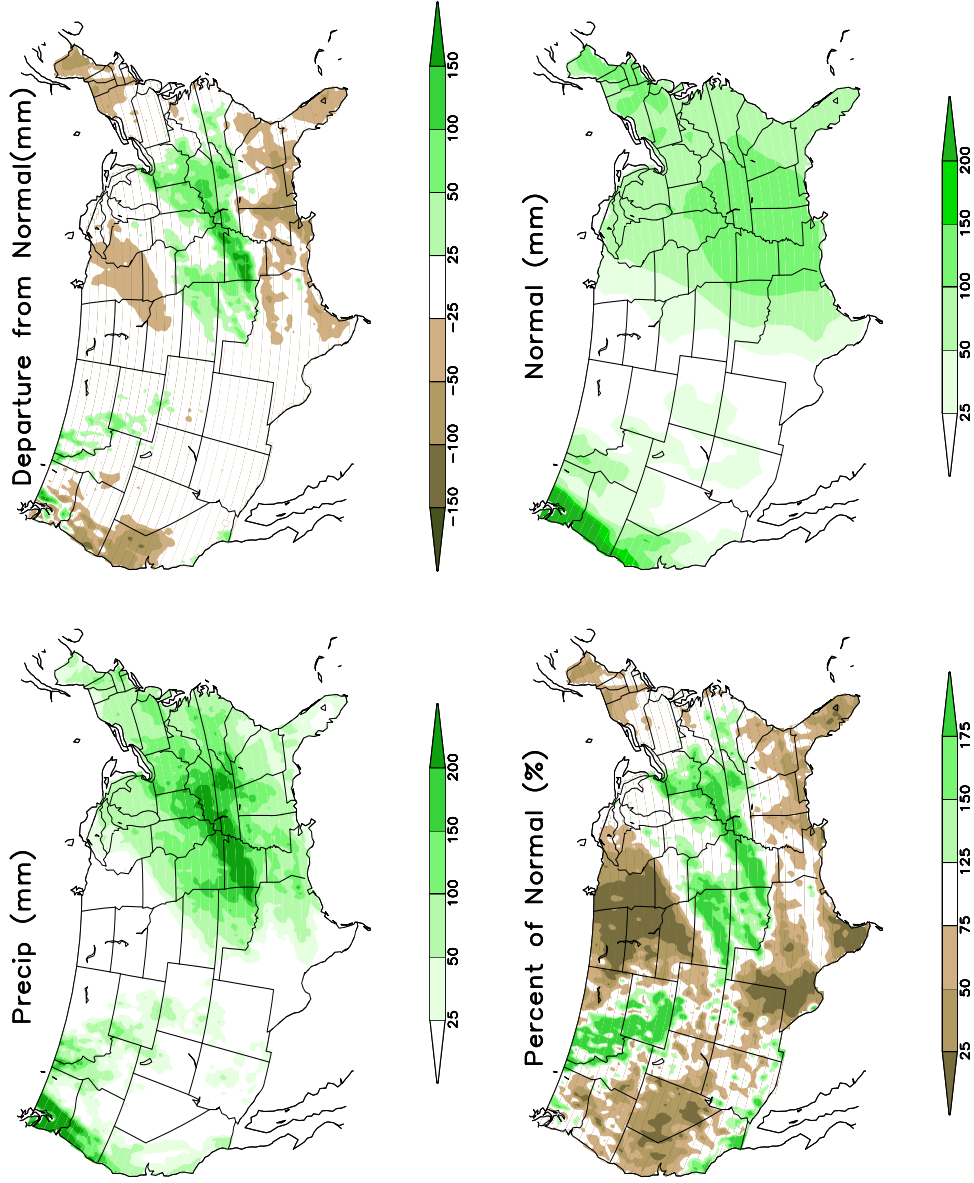

FIGURE E6. Observed precipitation (upper left), departure from average (upper right), percent of average (lower left), and average precipitation (lower right) for NOV 2011. The units are given on each panel. Base period for averages is 1981–2010. Results are based on CPC's U. S. daily precipitation analysis, which is available at <http://www.cpc.ncep.noaa.gov/products/precip/realtime>.

## Monthly Teleconnection Indices

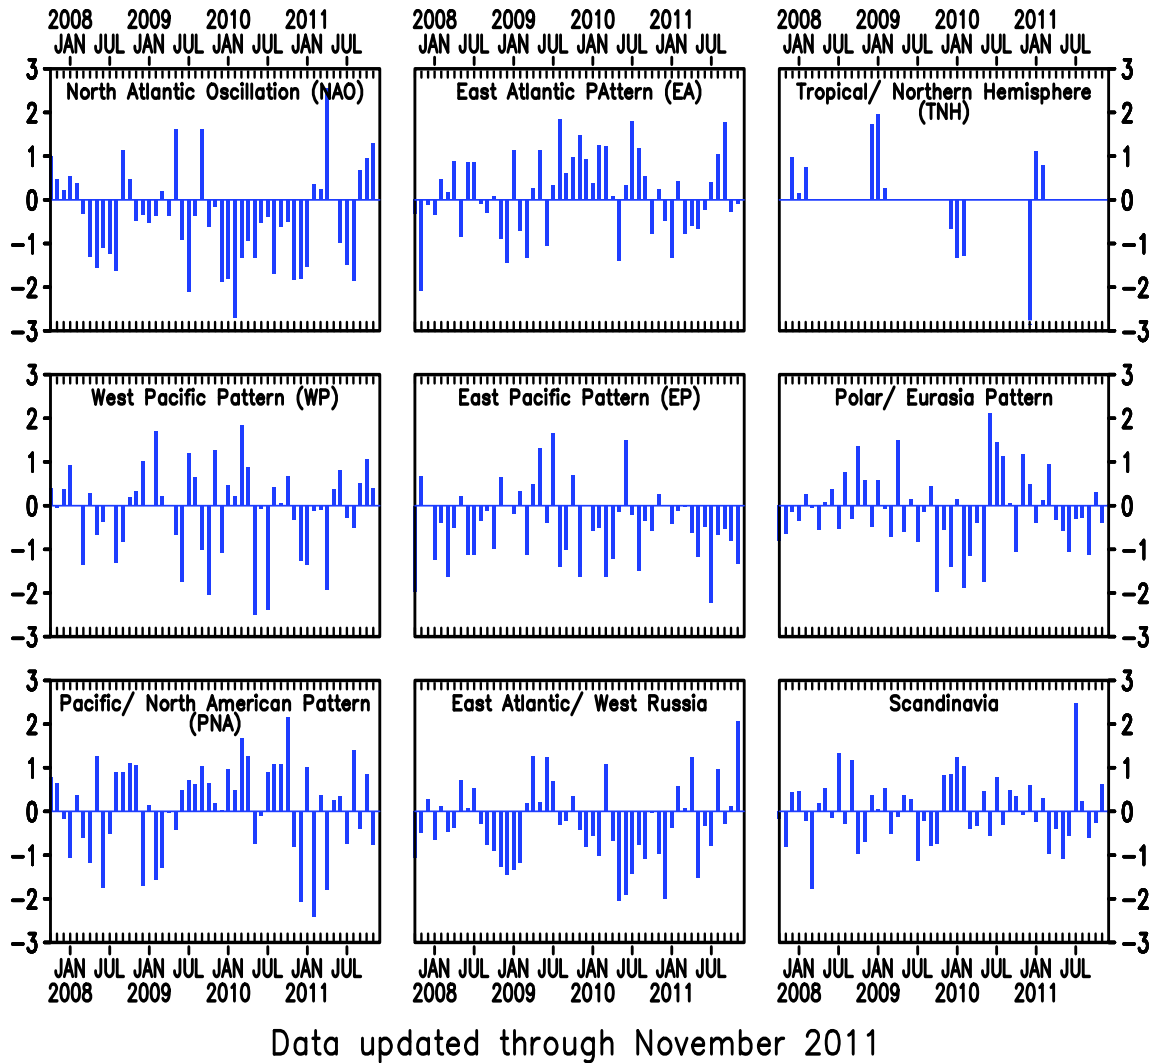

FIGURE E7. Standardized monthly Northern Hemisphere teleconnection indices. The teleconnection patterns are calculated from a Rotated Principal Component Analysis (RPCA) applied to monthly standardized 500-hPa height anomalies during the 1981-2010 base period. To obtain these patterns, ten leading un-rotated modes are first calculated for each calendar month by using the monthly height anomaly fields for the three-month period centered on that month: [i.e., The July modes are calculated from the June, July, and August standardized monthly anomalies]. A Varimax spatial rotation of the ten leading un-rotated modes for each calendar month results in 120 rotated modes (12 months x 10 modes per month) that yield ten primary teleconnection patterns. The teleconnection indices are calculated by first projecting the standardized monthly anomalies onto the teleconnection patterns corresponding to that month (eight or nine teleconnection patterns are seen in each calendar month). The indices are then solved for simultaneously using a Least-Squares approach. In this approach, the indices are the solution to the Least-Squares system of equations which explains the maximum spatial structure of the observed height anomaly field during the month. The indices are then standardized for each pattern and calendar month independently. No index value exists when the teleconnection pattern does not appear as one of the ten leading rotated EOF's valid for that month.

Sea-Level Pressure and Anomaly

FIGURE E14. Southern Hemisphere mean and anomalous sea level pressure(CDAS/Reanalysis) for NOV 2011. Mean values are denoted by solid contours drawn at an interval of 4 hPa. Anomaly contour interval is 2 hPa with values less (greater) than -2 hPa (2 hPa) indicated by dark (light) shading. Anomalies are calculated as departures from the 1981-2010 base period monthly means.

November 2011  
500-hPa Height and Anomaly

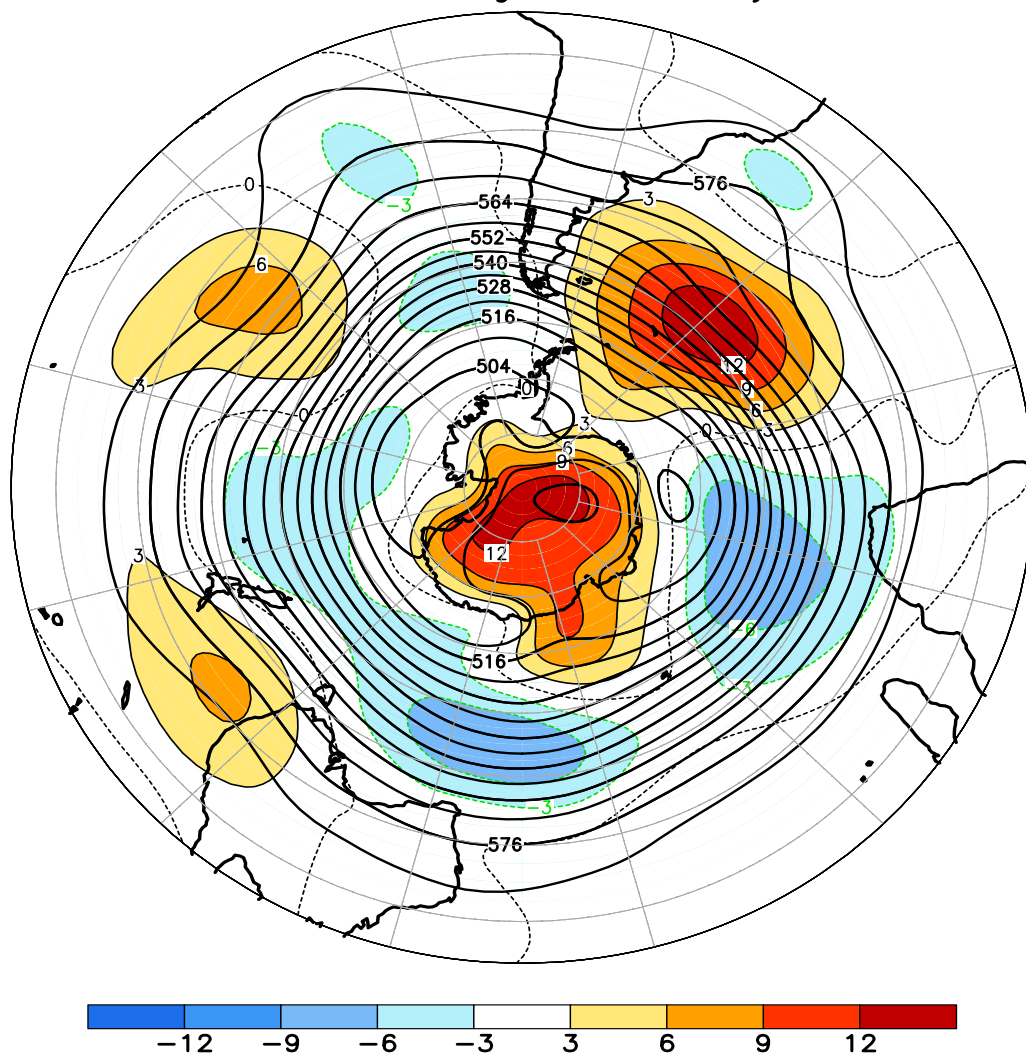

FIGURE E15. Southern Hemisphere mean and anomalous 500-hPa geopotential height (CDAS/Reanalysis) for NOV 2011. Mean heights are denoted by solid contours drawn at an interval of 6 dam. Anomaly contour interval is 3 dam with values less (greater) than -3 dam (3 dam) indicated by dark (light) shading. Anomalies are calculated as departures from the 1981-2010 base period monthly means.

November 2011  
300-hPa Wind

300-hPa Wind Anomaly

FIGURE E16. Southern Hemisphere mean (left) and anomalous (right) 300-hPa vector wind (CDAS/Reanalysis) for NOV 2011. Mean (anomaly) isotach contour interval is 10 (5)  $\text{ms}^{-1}$ . Values greater than 30  $\text{ms}^{-1}$  (left) and 10  $\text{ms}^{-1}$  (rights) are shaded. Anomalies are departures from the 1981-2010 base period monthly means.

November 2011  
500-hPa: Percentage of Anomaly Days

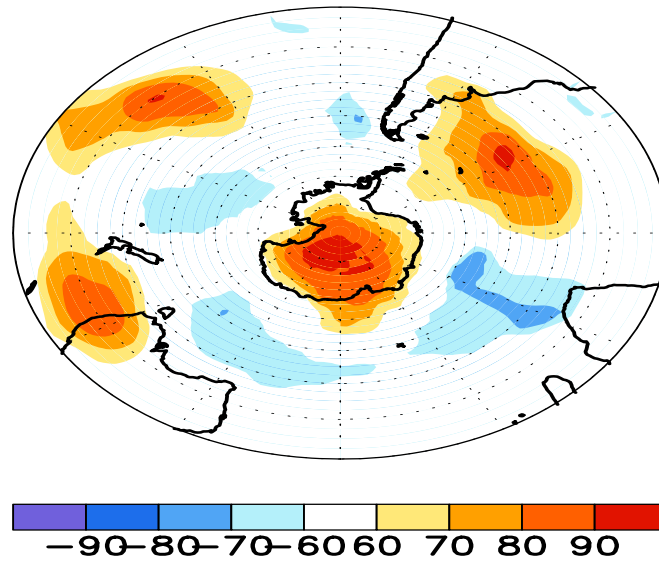

FIGURE E17. Southern Hemisphere percentage of days during NOV 2011 in which 500-hPa height anomalies greater than 15 m (red) and less than -15 m (blue) were observed. Values greater than 70% are shaded and contour in-

November 2011  
500-hPa Height Anomalies: 40.0S

FIGURE E18. Southern Hemisphere: Daily 500-hPa height anomalies for NOV 2011 averaged over the 5° latitude band centered on 40°S. Positive values are indicated by solid contours and dark shading. Negative values are indicated by dashed contours and light shading. Contour interval is 60 m. Anomalies are departures from the 1981-2010 base period daily means.

November 2011  
Height Anomalies

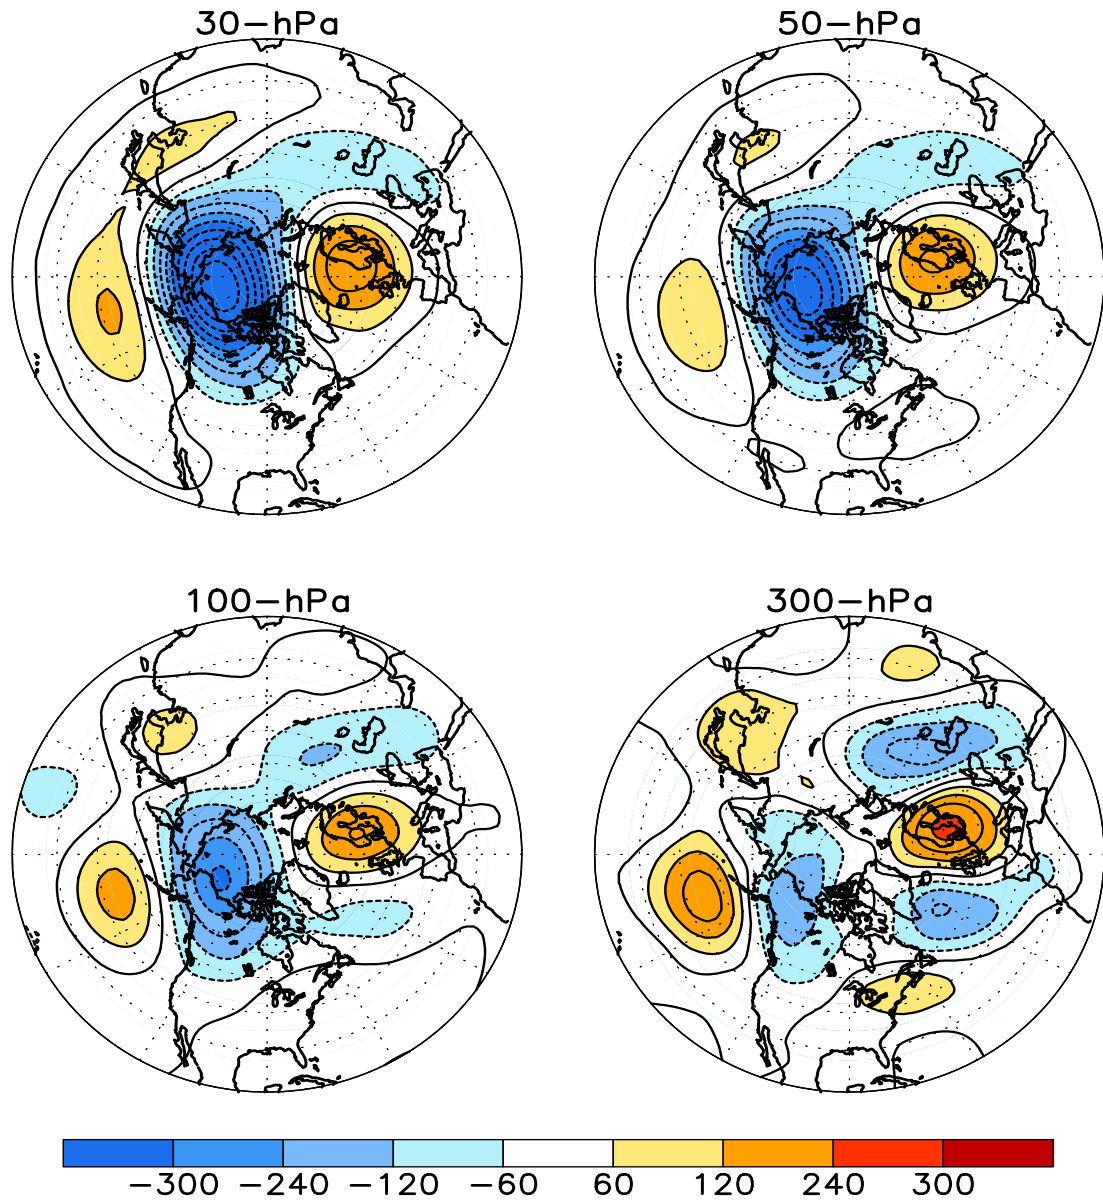

FIGURE S1. Stratospheric height anomalies (m) at selected levels for NOV 2011. Positive values are indicated by solid contours and dark shading. Negative values are indicated by dashed contours and light shading. Contour interval is 60 m. Anomalies are calculated from the 1981-2010 base period means. Winter Hemisphere is shown.

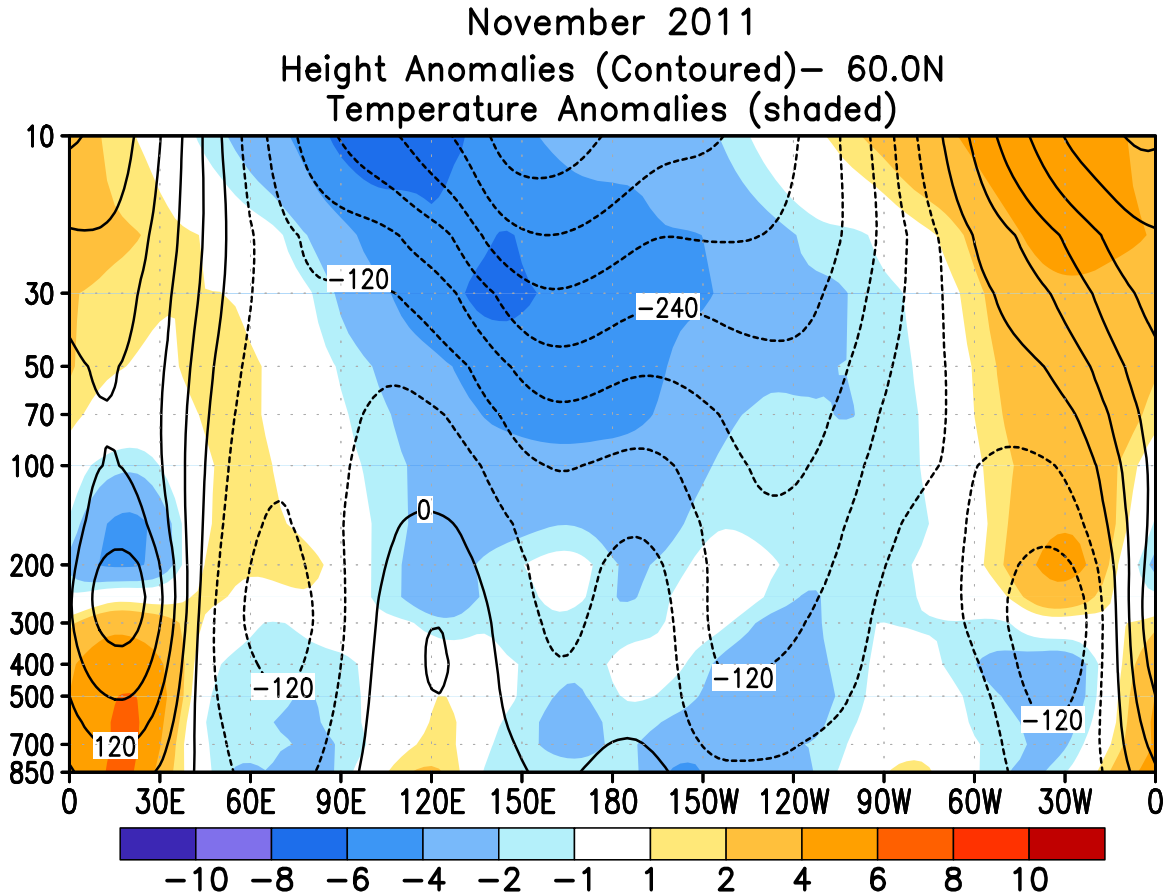

FIGURE S2. Height-longitude sections during NOV 2011 for height anomalies (contour) and temperature anomalies (shaded). In both panels, positive values are indicated by solid contours and dark shading, while negative anomalies are indicated by dashed contours and light shading. Contour interval for height anomalies is 60 m and for temperature anomalies is 2°C. Anomalies are calculated from the 1981-2010 base period monthly means. Winter Hemisphere is shown.

### 50hPa SON Mean Temperature Anomalies

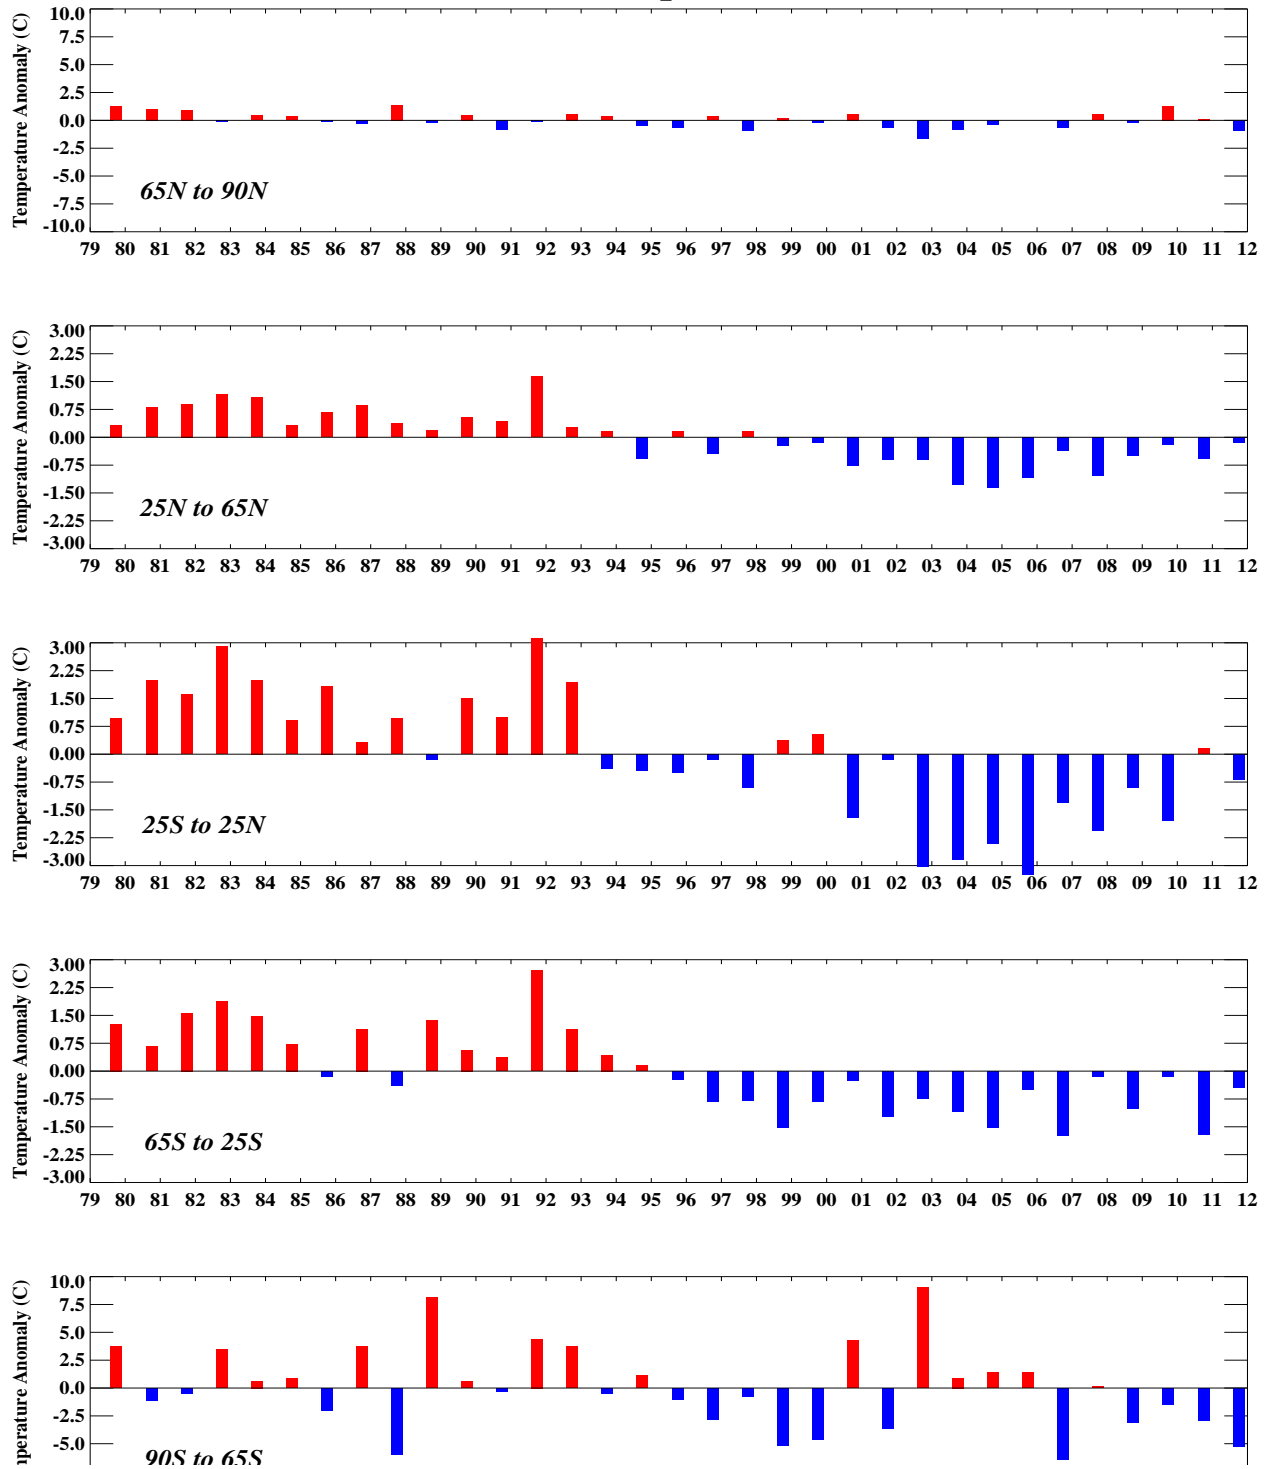

FIGURE S3. Seasonal mean temperature anomalies at 50-hPa for the latitude bands 65°–90°N, 25°–65°N, 25°N–25°S, 25°–65°S, 65°–90°S. The seasonal mean is comprised of the most recent three months. Zonal anomalies are taken from the mean of the entire data set.

### Zonal Mean Temperature for 2010 & 2011

FIGURE S4. Daily mean temperatures at 10-hPa and 2-hPa (thick line) in the region 65°–90°N and 65°–90°S for the past two years. Dashed line depicts the 1981–2010 base period daily mean. Thin solid lines depict the daily extreme maximum and minimum temperatures.

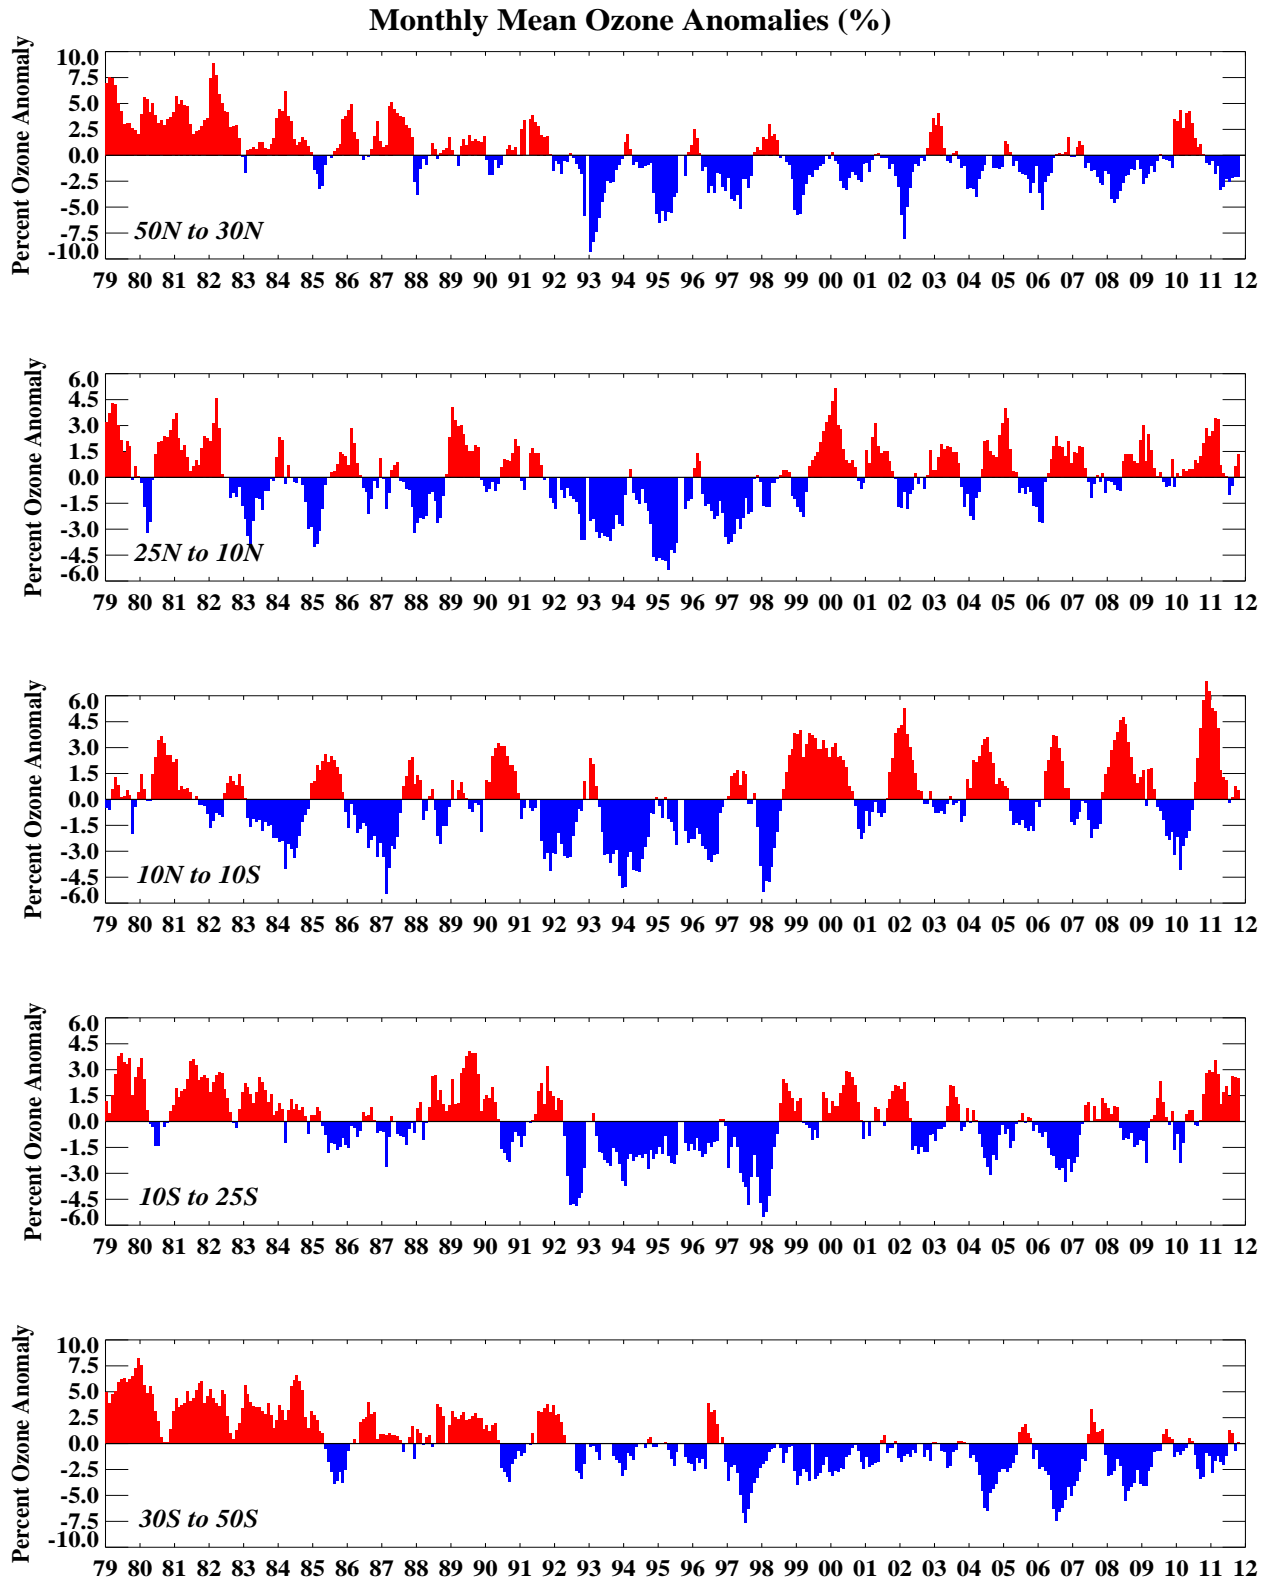

FIGURE S5. Monthly ozone anomalies (percent) from the long term monthly means for five zones: 50N-30N (NH mid-latitudes), 25N-10N (NH tropical surf zone), 10N-10S (Equatorial-QBO zone), 10S-25S (SH tropical surf zone), and 30S-50S (SH mid-latitudes). The long term monthly means are determined from the entire data set

# NOVEMBER PERCENT DIFF (2011 - AVG[79-86])

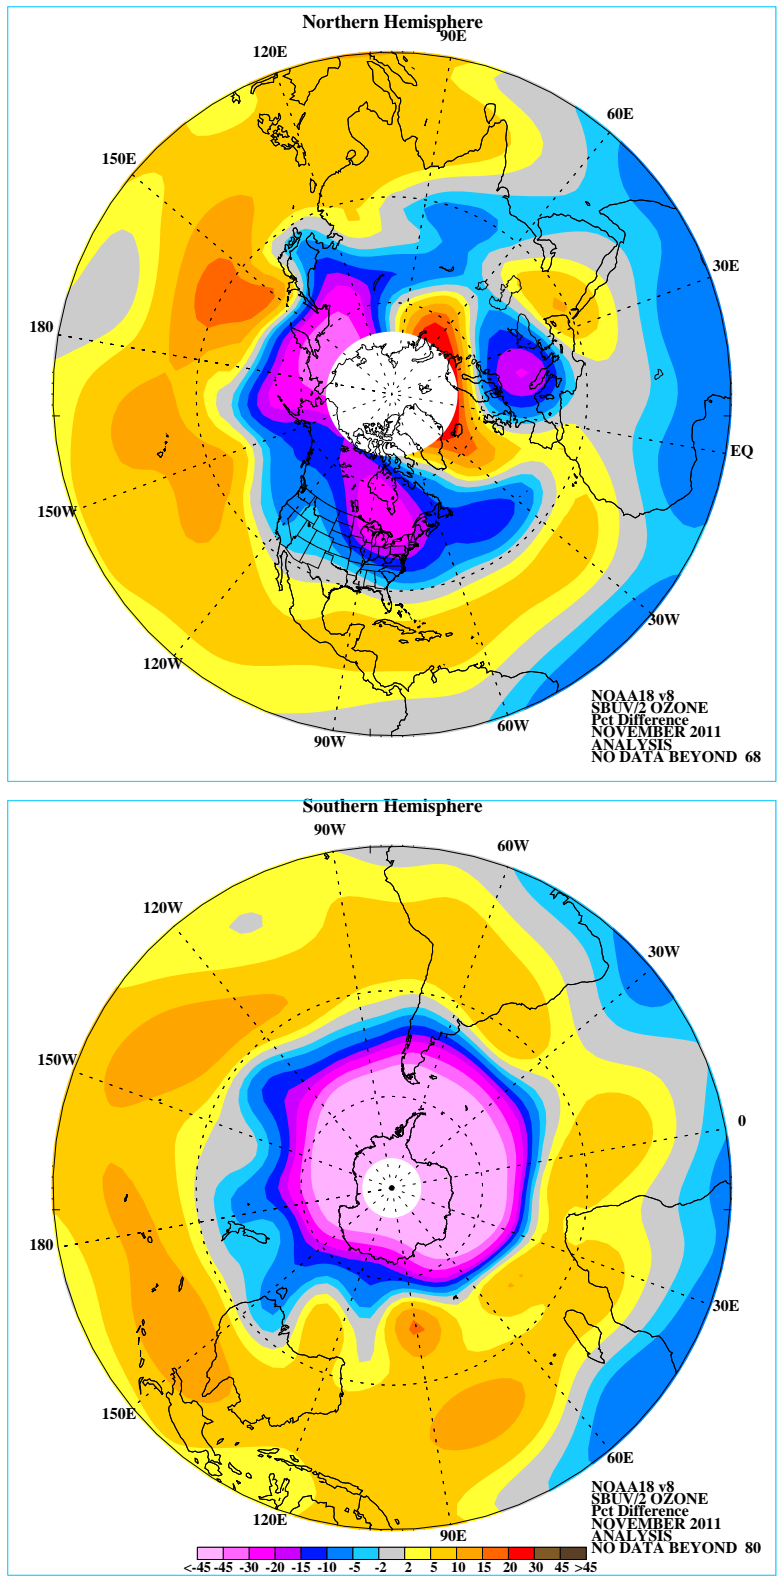

FIGURE S6. Northern (top) and Southern (bottom) Hemisphere total ozone anomaly (percent difference from monthly mean for the period 1979-1986). The region near the winter pole has no SBUV/2 data.

# Fz at 100 hPa (Oct. 2011)

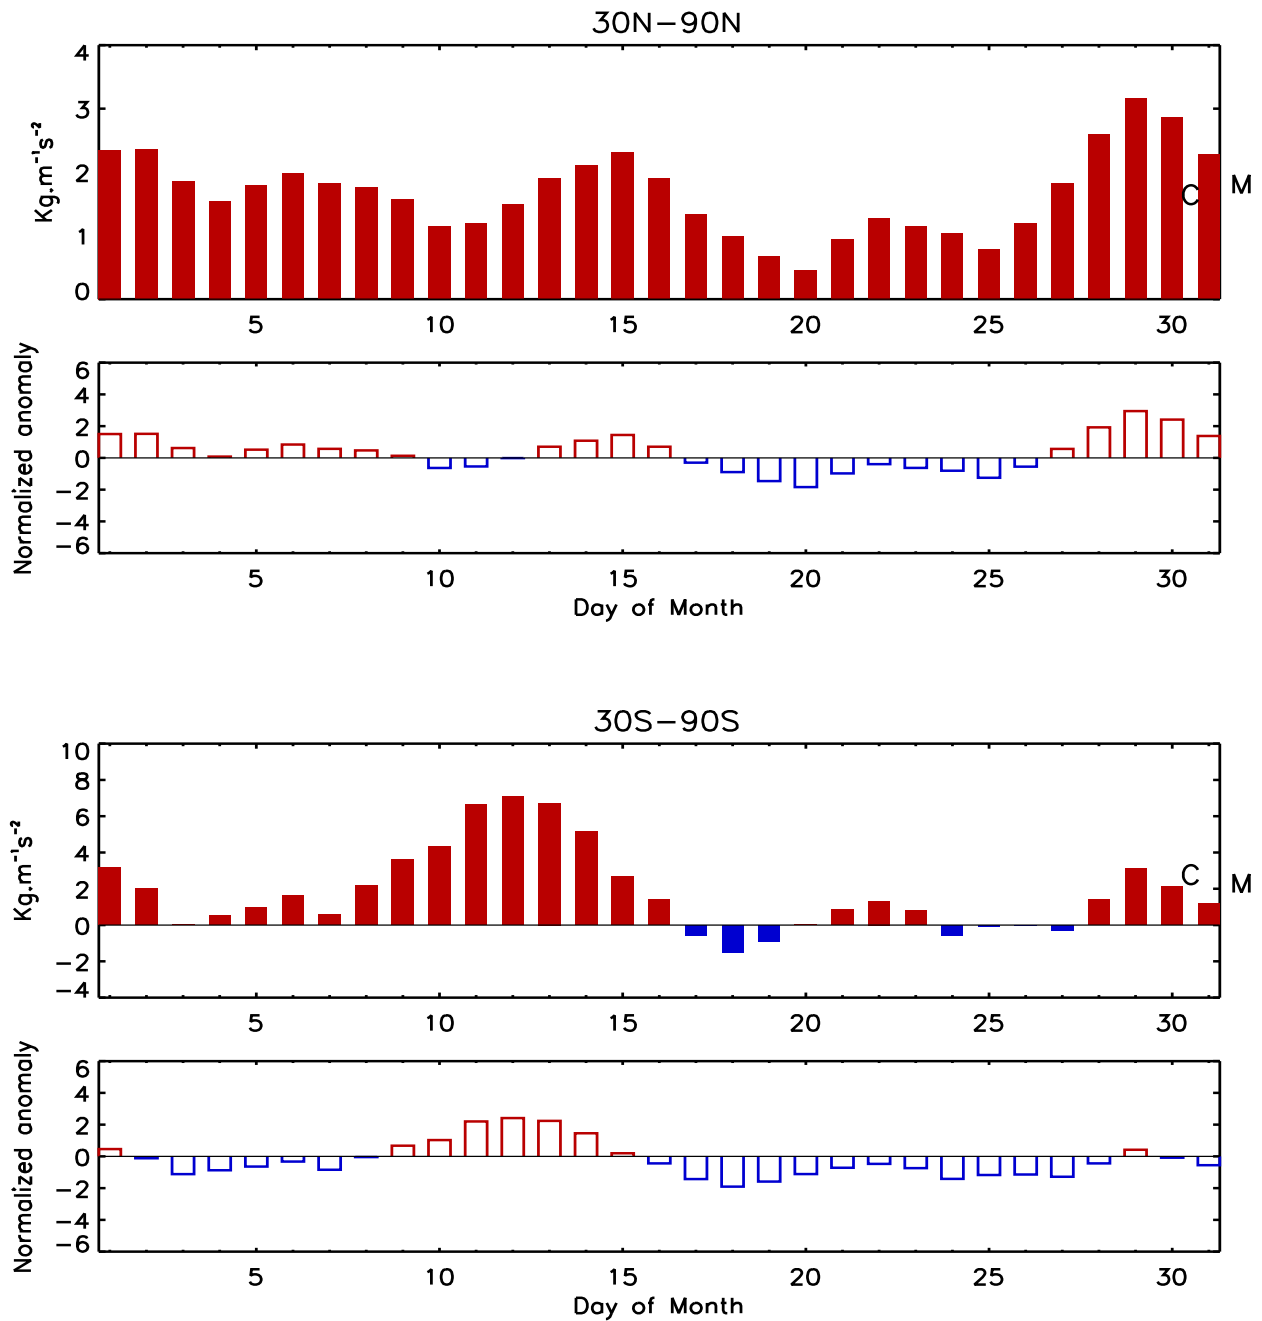

FIGURE S7. Daily vertical component of EP flux (which is proportional to the poleward transport of heat or upward transport of potential energy by planetary wave) at 100 hPa averaged over (top) 30°N–90°N and (bottom) 30°S–90°S for NOV 2011. The EP flux unit ( $\text{kg m}^{-1} \text{s}^{-2}$ ) has been scaled by multiplying a factor of the Brunt Vaisala frequency divided by the Coriolis parameter and the radius of the earth. The letter ‘M’ indicates the current monthly mean value and the letter ‘C’ indicates the climatological mean value. Additionally, the normalized departures from the monthly climatological EP flux values are shown.

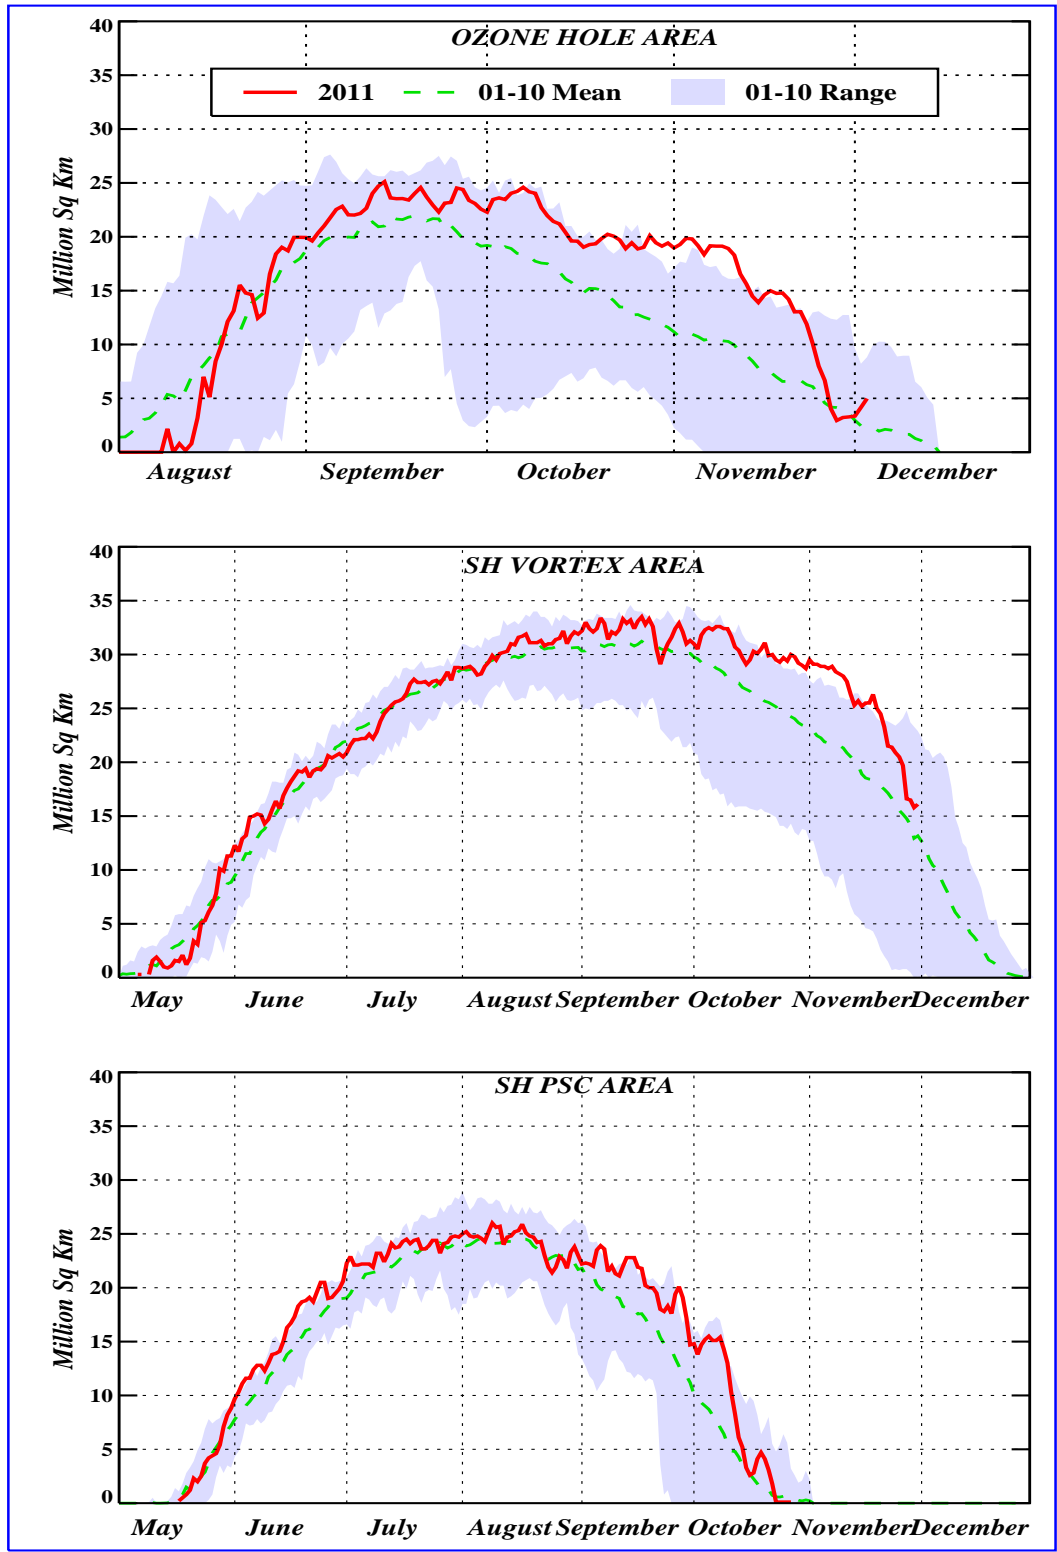

FIGURE S8. Daily time series showing the size of the SH polar vortex (representing the area enclosed by the 32 PVU contour on the 450K isentropic surface), and the areal coverage of temperatures < -78C on the 450K isentropic surface.

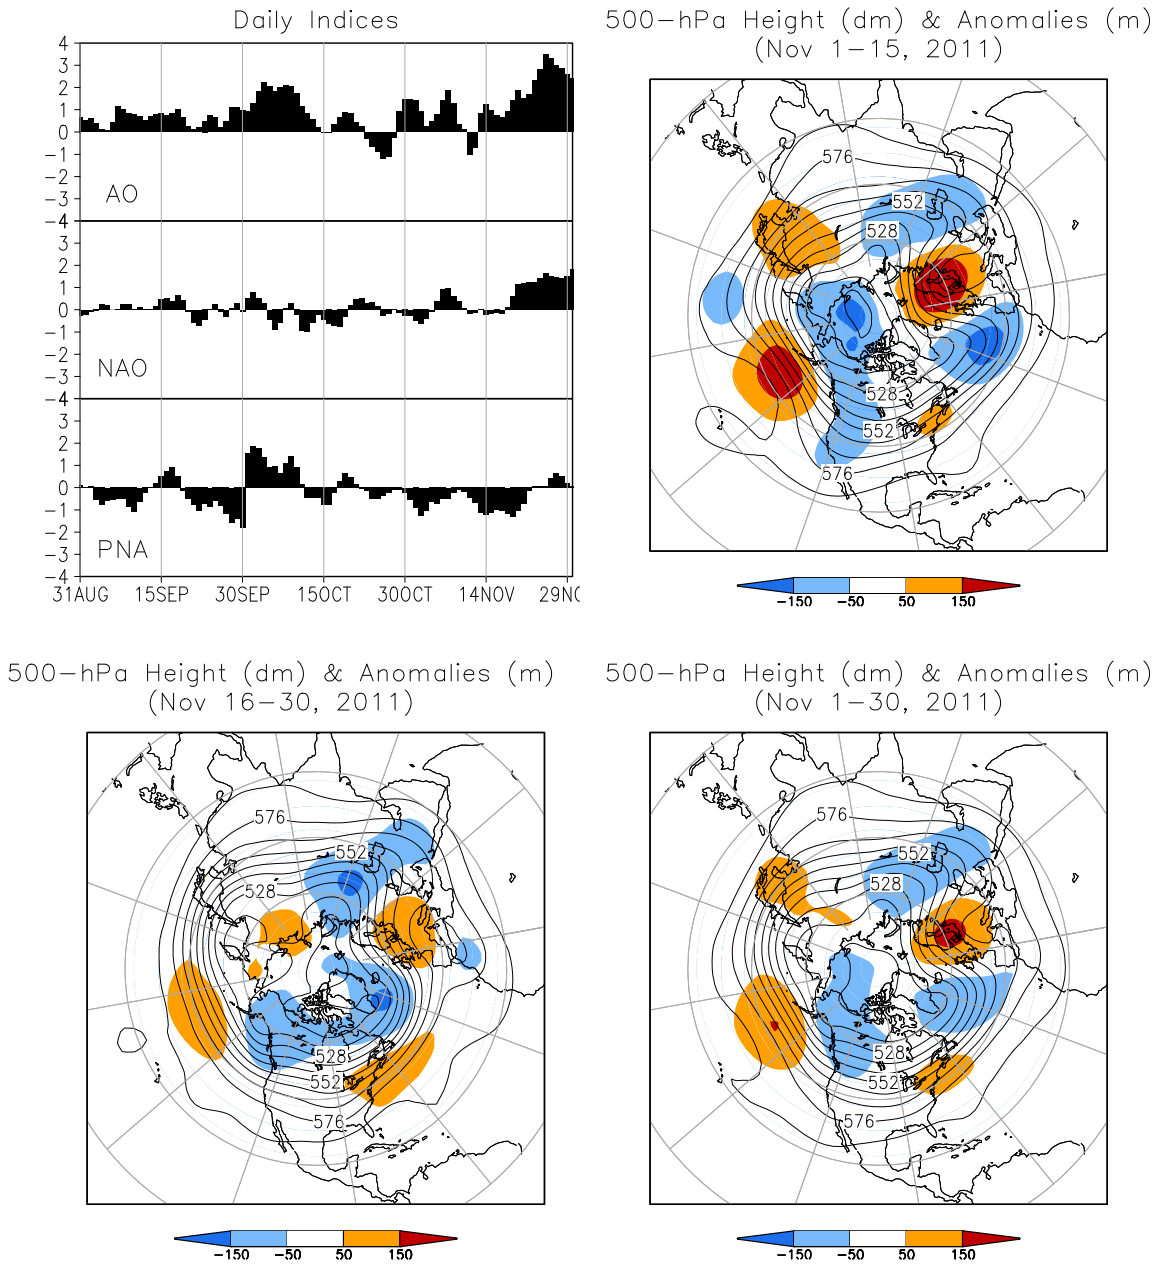

FIGURE A2.1. (a) Daily amplitudes of the Arctic Oscillation (AO) the North Atlantic Oscillation (NAO), and the Pacific-North American (PNA) pattern. The pattern amplitudes for the AO, (NAO, PNA) are calculated by projecting the daily 1000-hPa (500-hPa) height anomaly field onto the leading EOF obtained from standardized time-series of daily 1000-hPa (500-hPa) height for all months of the year. The base period is 1981–2010.

(b-d) Northern Hemisphere mean and anomalous 500-hPa geopotential height (CDAS/Reanalysis) for selected periods during NOV 2011 are shown in the remaining 3 panels. Mean heights are denoted by solid contours drawn at an interval of 8 dam. Dark (light) shading corresponds to anomalies greater than 50 m (less than -50 m). Anomalies are calculated as departures from the 1981-2010 base period daily means.

**SSM/I Snow Cover for Nov 2011**  
**anomaly based on departure from 1987–2010 baseline**

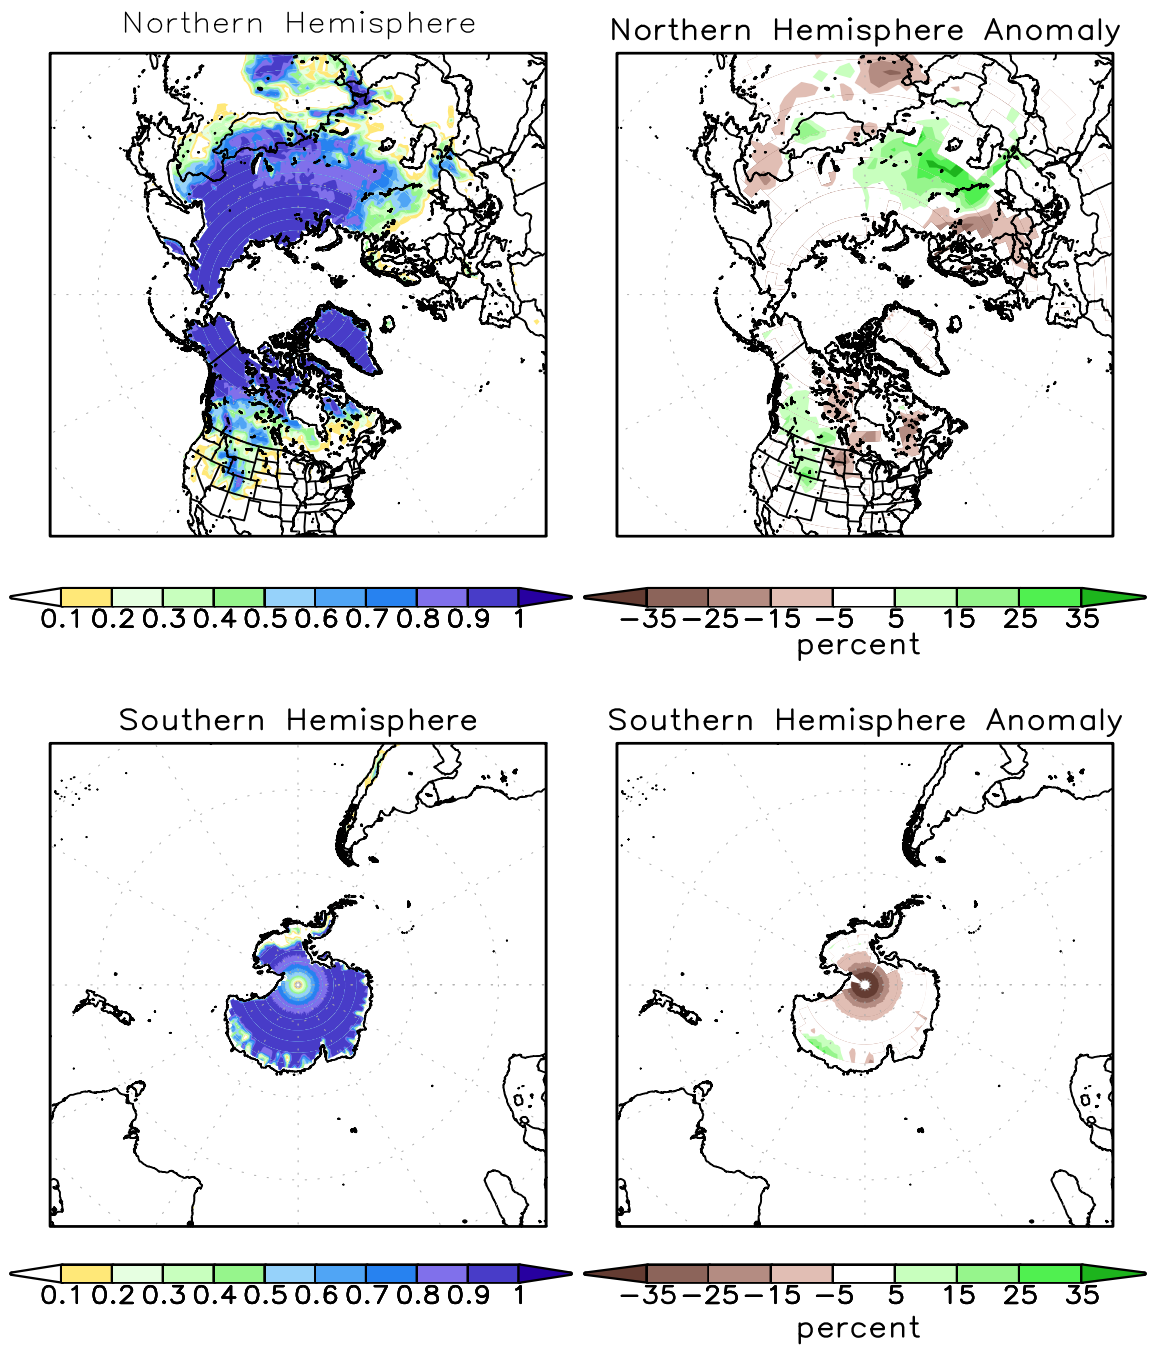

FIGURE A2.2. SSM/I derived snow cover frequency (%) (left) and snow cover anomaly (%) (right) for the month of NOV 2011 based on 1987 - 2010 base period for the Northern Hemisphere (top) and Southern Hemisphere (bottom). It is generated using the algorithm described by Ferraro et. al, 1996, Bull. Amer. Meteor. Soc., vol 77, 891-905.
