Summary

ENSO Alert System Status: La Niña Advisory

La Niña conditions are present.*

Equatorial sea surface temperatures (SSTs) are below average across the central and eastern Pacific Ocean.

La Niña conditions are predicted to continue (~65%-75% chance) at least through the Northern Hemisphere winter 2017-18.*

* Note: These statements are updated once a month (2nd Thursday of each month) in association with the ENSO Diagnostics Discussion, which can be found by clicking [here](#).
During January and February 2017, above-average SSTs expanded in the eastern Pacific Ocean.

From mid April to July 2017, near-to-above average SSTs spanned most of the equatorial Pacific.

During August 2017, above-average SSTs dissipated east of the date line.

Since September 2017, SSTs have been near-to-below average across the central and eastern Pacific Ocean.

Recently, negative SST anomalies persist over the central and eastern equatorial Pacific.
Niño Region SST Departures (°C) Recent Evolution

The latest weekly SST departures are:

- Niño 4: -0.1°C
- Niño 3.4: -0.8°C
- Niño 3: -1.1°C
- Niño 1+2: -1.2°C
During the last four weeks, equatorial SSTs were below average across the central and eastern Pacific Ocean, and above average in the far western Pacific.
Global SST Departures (°C) During the Last Four Weeks

During the last four weeks, equatorial SSTs were above average in the far western Pacific, eastern Atlantic, and eastern Indian Oceans. SSTs were below average in the central and eastern Pacific Ocean.
During the last four weeks, below-average SSTs persisted across the central and eastern Pacific Ocean.
Change in Weekly SST Departures over the Last Four Weeks

During the last four weeks, changes in equatorial SST anomalies were mostly negative across the central and east-central Pacific Ocean.
Upper-Ocean Conditions in the Equatorial Pacific

The basin-wide equatorial upper ocean (0-300 m) heat content is greatest prior to and during the early stages of a Pacific warm (El Niño) episode (compare top 2 panels), and least prior to and during the early stages of a cold (La Niña) episode.

The slope of the oceanic thermocline is least (greatest) during warm (cold) episodes.

Recent values of the upper-ocean heat anomalies (below average) and thermocline slope index (above average) reflect La Niña conditions.

The monthly thermocline slope index represents the difference in anomalous depth of the 20°C isotherm between the western Pacific (160°E-150°W) and the eastern Pacific (90°-140°W).
Negative subsurface temperature anomalies were present through December 2016. Positive anomalies with large fluctuations in amplitude were present from mid-January through mid-July 2017. Since mid-July, anomalies decreased and have remained negative.
Sub-Surface Temperature Departures in the Equatorial Pacific

In the last two months, negative subsurface temperature anomalies have persisted across the central and eastern Pacific Ocean.

Recently, the strongest negative anomalies are between 160°W-80°W.
Tropical OLR and Wind Anomalies During the Last 30 Days

Negative OLR anomalies (enhanced convection and precipitation) were evident over Indonesia. Positive OLR anomalies (reduced convection and precipitation) were present over the central Pacific Ocean.

Low-level (850-hPa) winds were anomalous easterly over the western tropical Pacific Ocean.

Upper-level (200-hPa) winds were anomalous westerly across most of the tropical Pacific Ocean.
Intraseasonal variability in the atmosphere (wind and pressure), which is often related to the Madden-Julian Oscillation (MJO), can significantly impact surface and subsurface conditions across the Pacific Ocean.

Related to this activity:

Significant weakening of the low-level easterly winds usually initiates an eastward-propagating oceanic Kelvin wave.
Weekly Heat Content Evolution in the Equatorial Pacific

From February 2017 through May 2017, positive subsurface temperature anomalies persisted in the western and eastern Pacific Ocean, with oceanic Kelvin waves resulting in temperature variability in the central Pacific. During August 2017, an upwelling Kelvin wave resulted in below-average sub-surface temperatures across the east-central and eastern equatorial Pacific. Since September 2017, negative sub-surface anomalies have persisted in those regions.

Equatorial oceanic Kelvin waves have alternating warm and cold phases. The warm phase is indicated by dashed lines. Down-welling and warming occur in the leading portion of a Kelvin wave, and up-welling and cooling occur in the trailing portion.
Low-level (850-hPa) Zonal (east-west) Wind Anomalies (m s\(^{-1}\))

Low-level easterly wind anomalies generally persisted over the central and western equatorial Pacific from May-October 2017.

From January-October 2017, westerly wind anomalies were generally observed over the eastern Pacific Ocean.

From mid-October to early November 2017, the Madden Julian Oscillation (MJO) disrupted the pattern, contributing to the eastward propagation of low-level wind anomalies.

Westerly Wind Anomalies (orange/red shading)
Easterly Wind Anomalies (blue shading)
Upper-level (200-hPa) Velocity Potential Anomalies

Since at least April 2017, anomalous upper-level divergence (green shading) generally persisted near Indonesia, while anomalous convergence (brown shading) persisted near the Date Line.

Eastward propagation of regions of upper-level divergence (green shading) and convergence (brown shading) is particularly evident from mid-July 2017 to mid-November 2017.

Unfavorable for precipitation (brown shading)
Favorable for precipitation (green shading)

Note: Eastward propagation is not necessarily indicative of the Madden-Julian Oscillation (MJO).
Outgoing Longwave Radiation (OLR) Anomalies

From mid-May to late July 2017, OLR anomalies were negative near Indonesia.

Since mid-August 2017, positive OLR anomalies have persisted over the central Pacific Ocean. Negative OLR anomalies have been more intermittent near the Maritime Continent.

Drier-than-average Conditions (orange/red shading)
Wetter-than-average Conditions (blue shading)
The ONI is based on SST departures from average in the Niño 3.4 region, and is a principal measure for monitoring, assessing, and predicting ENSO.

Defined as the three-month running-mean SST departures in the Niño 3.4 region. Departures are based on a set of improved homogeneous historical SST analyses (Extended Reconstructed SST - ERSST.v5). The SST reconstruction methodology is described in Huang et al., 2017, J. Climate, vol. 30, 8179-8205.)

It is one index that helps to place current events into a historical perspective
NOAA Operational Definitions for El Niño and La Niña

El Niño: characterized by a positive ONI greater than or equal to +0.5°C.

La Niña: characterized by a negative ONI less than or equal to -0.5°C.

By historical standards, to be classified as a full-fledged El Niño or La Niña episode, these thresholds must be exceeded for a period of at least 5 consecutive overlapping 3-month seasons.

CPC considers El Niño or La Niña conditions to occur when the monthly Niño3.4 OISST departures meet or exceed +/- 0.5°C along with consistent atmospheric features. These anomalies must also be forecasted to persist for 3 consecutive months.
ONI (°C): Evolution since 1950

The most recent ONI value (August - October 2017) is -0.4°C.
Historical El Niño and La Niña Episodes Based on the ONI computed using ERSST.v5

Recent Pacific warm (red) and cold (blue) periods based on a threshold of +/- 0.5 °C for the Oceanic Niño Index (ONI) [3 month running mean of ERSST.v5 SST anomalies in the Nino 3.4 region (5N-5S, 120-170W)]. For historical purposes, periods of below and above normal SSTs are colored in blue and red when the threshold is met for a minimum of 5 consecutive over-lapping seasons.

The ONI is one measure of the El Niño-Southern Oscillation, and other indices can confirm whether features consistent with a coupled ocean-atmosphere phenomenon accompanied these periods. The complete table going back to DJF 1950 can be found here.

</table>
La Niña conditions are predicted to continue (~65%-75% chance) at least through the Northern Hemisphere winter 2017-18, with a 51% chance of continuation through February-April 2018.
The multi-model averages predict La Niña to persist into early 2018.
The CFS.v2 ensemble mean (black dashed line) favors La Niña through March-May 2018.
Atmospheric anomalies over the North Pacific and North America During the Last 60 Days

Since late September 2017, a retracted jet stream over the North Pacific and strong anomalous ridge has been mostly associated with below-average heights (and temperatures) downstream over Canada and parts of the northern United States.

Since late October anomalous ridging (and above-average temperatures) have generally prevailed over the southwestern U.S.

The overall pattern has been generally consistent with La Niña.
