Tropical Highlights - December 2009

Sea surface temperature (SST) anomalies during December 2009 continued to increase across much of the central and eastern equatorial Pacific Ocean (**Fig. T18**). Consequently, all of the monthly Niño-region SST indices were above +1.4°C, except for the Niño 1+2 index (**Table T2, Fig. T5**). The oceanic thermocline, measured by the depth of the 20°C isotherm, remained deeper than average across the equatorial Pacific (**Figs. T15, T16**), with sub-surface temperatures in the eastern Pacific reaching +2°C to +0.5°C above average (**Fig. T17**).

During December 2009, convection was suppressed across Indonesia and enhanced over the western and central equatorial Pacific (**Figs. T25, T26 and E3**). Equatorial low-level westerly and upper-level easterly wind anomalies (**Figs. T20 and T21**) were also consistent with El Niño. Overall, the oceanic and atmospheric anomalies reflected a strong El Niño.

For the latest status of the ENSO cycle see the ENSO Diagnostic Discussion at:
http://www.cpc.ncep.noaa.gov/products/analysis_monitoring/enso_advisory/index.html

TABLE T1 - Atmospheric index values for the most recent 12 months. Indices are standardized by the mean annual standard deviation, except for the Tahiti and Darwin SLP anomalies which are in units of hPa. Positive (negative) values of 200-hPa zonal wind index imply westerly (easterly) anomalies. Positive (negative) values of 850-hPa zonal wind indices imply easterly (westerly) anomalies.

TABLE T2. Mean and anomalous sea surface temperature (°C) for the most recent 12 months. Anomalies are departures from the 1971–2000 adjusted OI climatology (Smith and Reynolds 1998, *J. Climate*, **11**, 3320–3323).

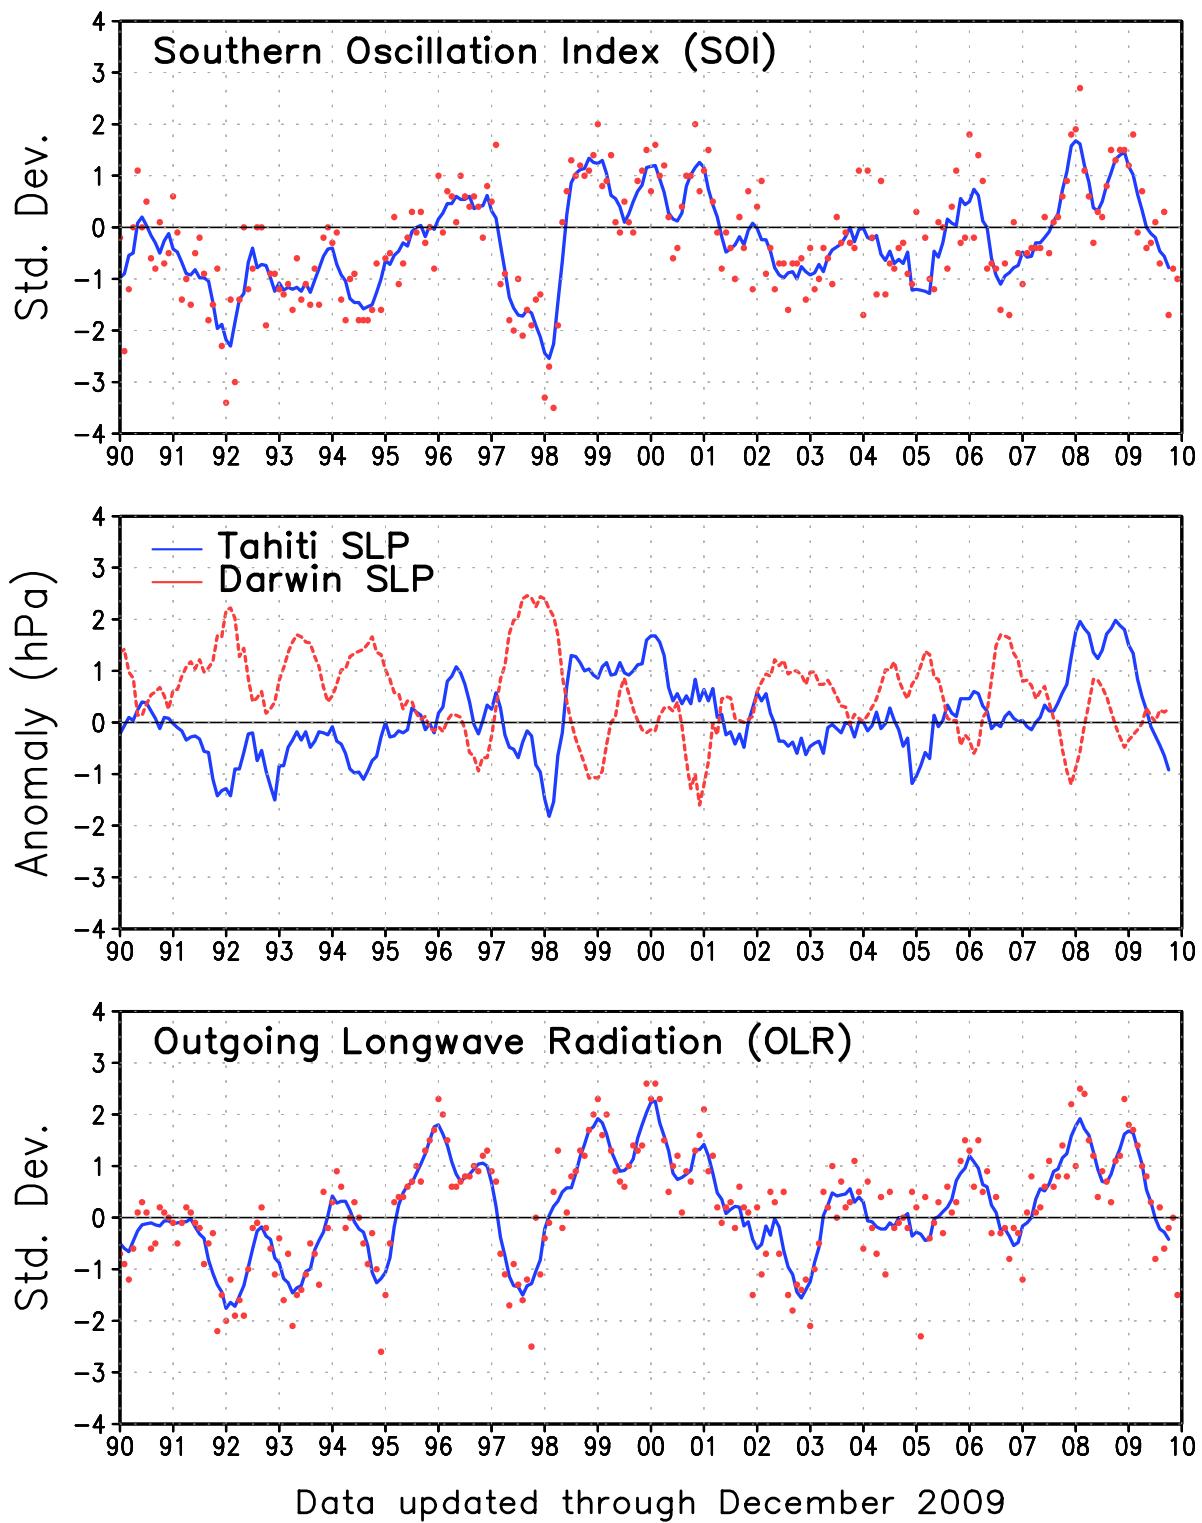

FIGURE T1. Five-month running mean of the Southern Oscillation Index (SOI) (top), sea-level pressure anomaly (hPa) at Darwin and Tahiti (middle), and outgoing longwave radiation anomaly (OLR) averaged over the area 5N-5S, 160E-160W (bottom). Anomalies in the top and middle panels are departures from the 1951-1980 base period means and are normalized by the mean annual standard deviation. Anomalies in the bottom panel are departures from the 1979-1995 base period means. Individual monthly values are indicated by “x”s in the top and bottom panels. The x-axis labels are centered on July.

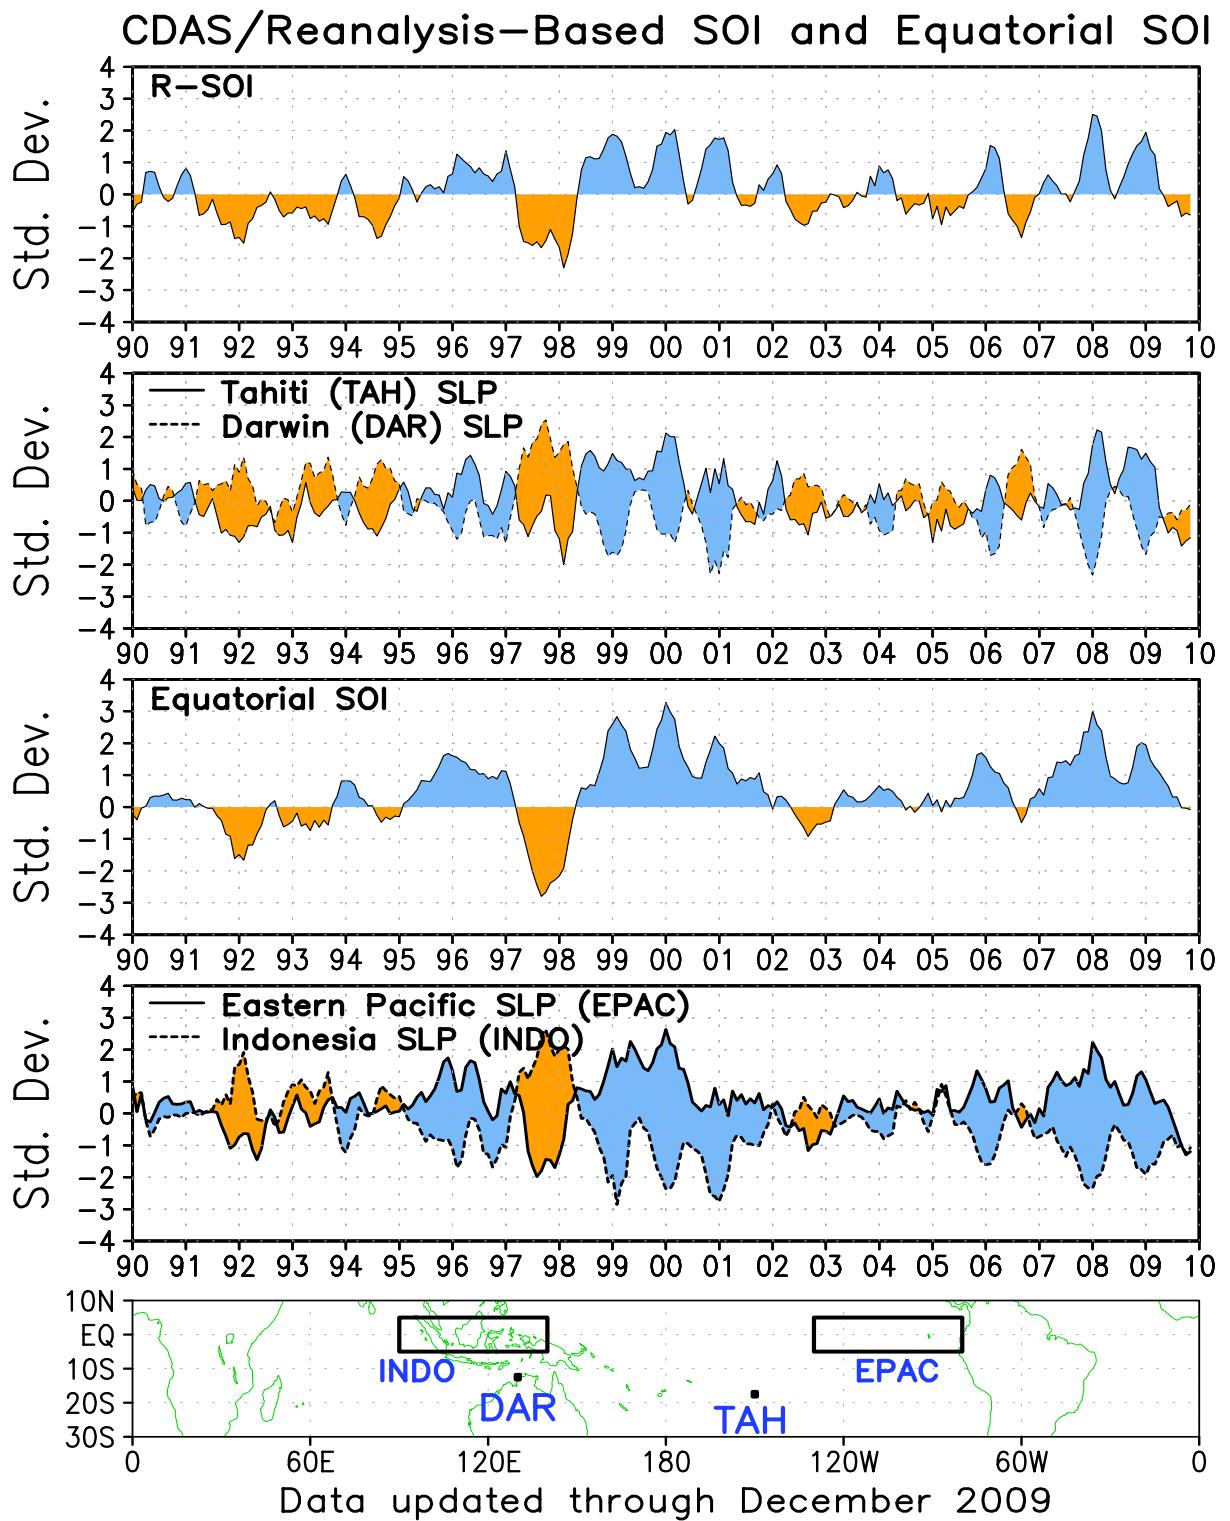

FIGURE T2. Three-month running mean of a CDAS/Reanalysis-derived (a) Southern Oscillation Index (RSOI), (b) standardized pressure anomalies near Tahiti (solid) and Darwin (dashed), (c) an equatorial SOI ([EPAC] - [INDO]), and (d) standardized equatorial pressure anomalies for (EPAC) (solid) and (INDO) (dashed). Anomalies are departures from the 1979–95 base period means and are normalized by the mean annual standard deviation. The equatorial SOI is calculated as the normalized difference between the standardized anomalies averaged between 5°N–5°S, 80°W–130°W (EPAC) and 5°N–5°S, 90°E–140°E (INDO).

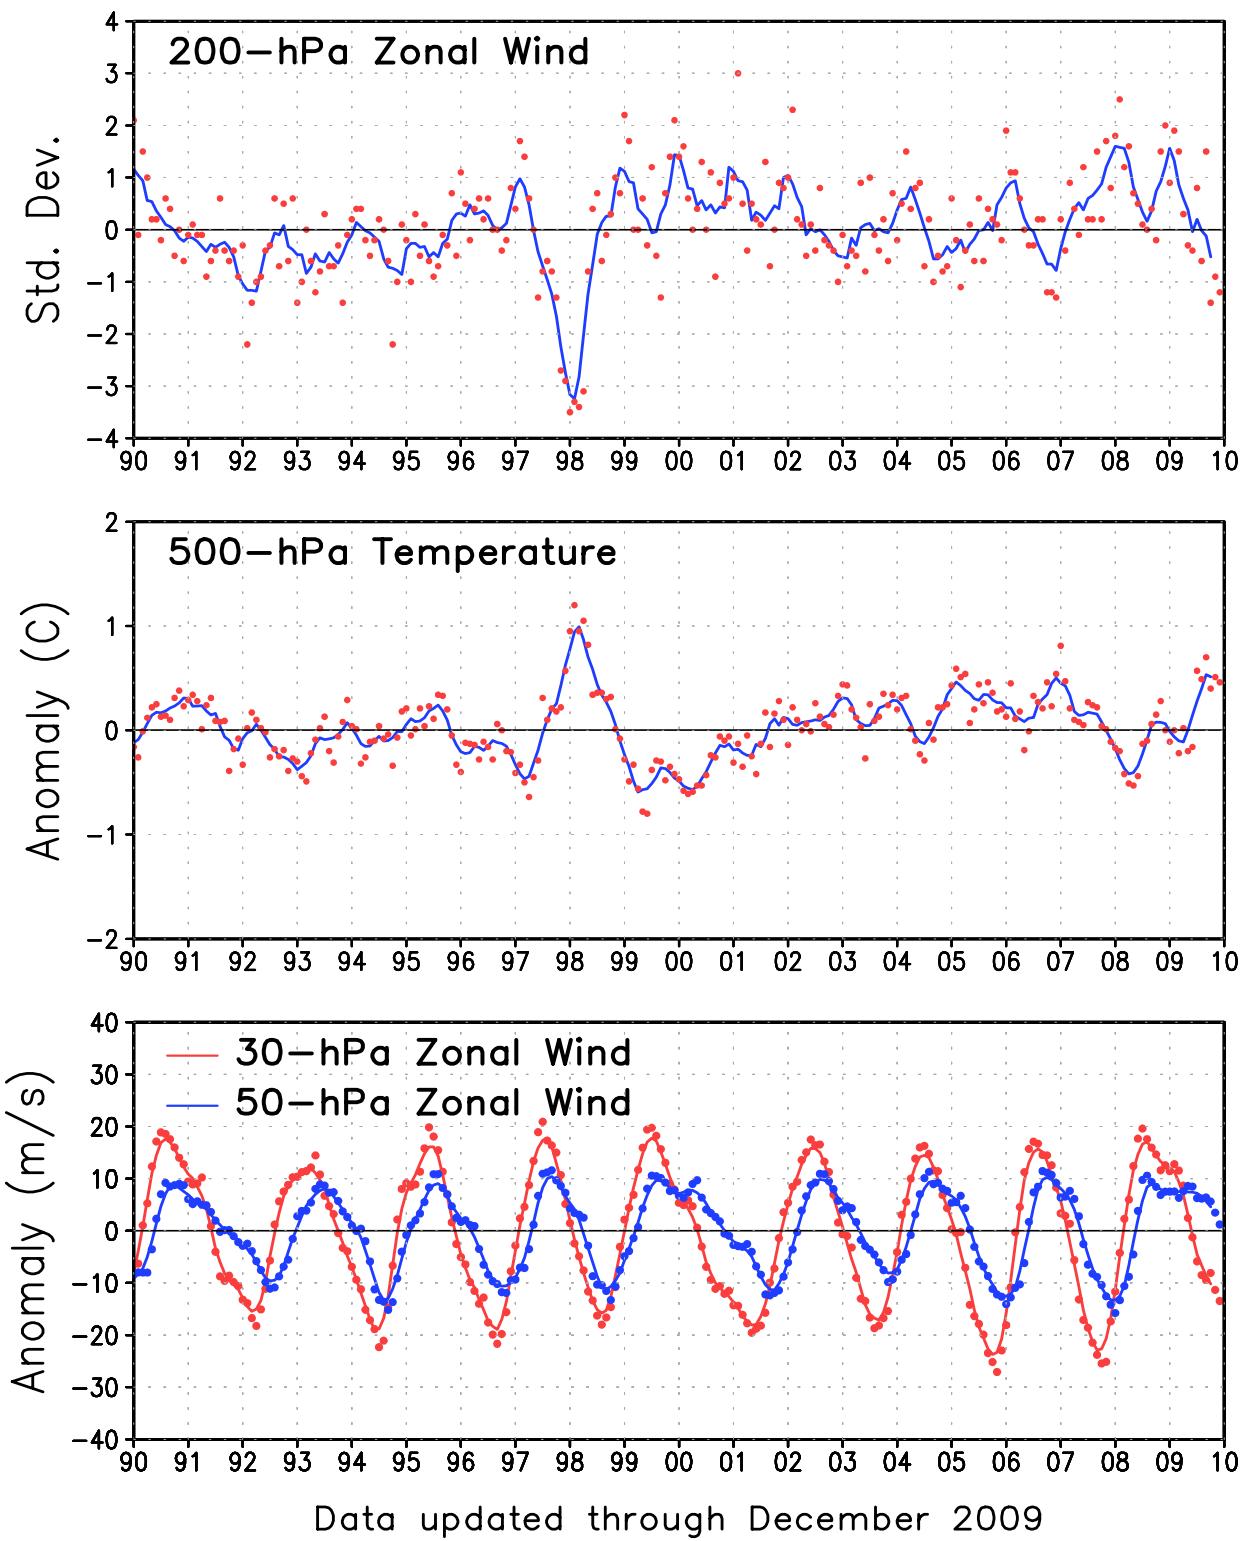

FIGURE T3. Five-month running mean (solid lines) and individual monthly mean (dots) of the 200-hPa zonal wind anomalies averaged over the area 5N-5S, 165W-110W (top), the 500-hPa virtual temperature anomalies averaged over the latitude band 20N-20S (middle), and the equatorial zonally-averaged zonal wind anomalies at 30-hPa (red) and 50-hPa (blue) (bottom). In the top panel, anomalies are normalized by the mean annual standard deviation. Anomalies are departures from the 1979-1995 base period means. The x-axis labels are centered on January.

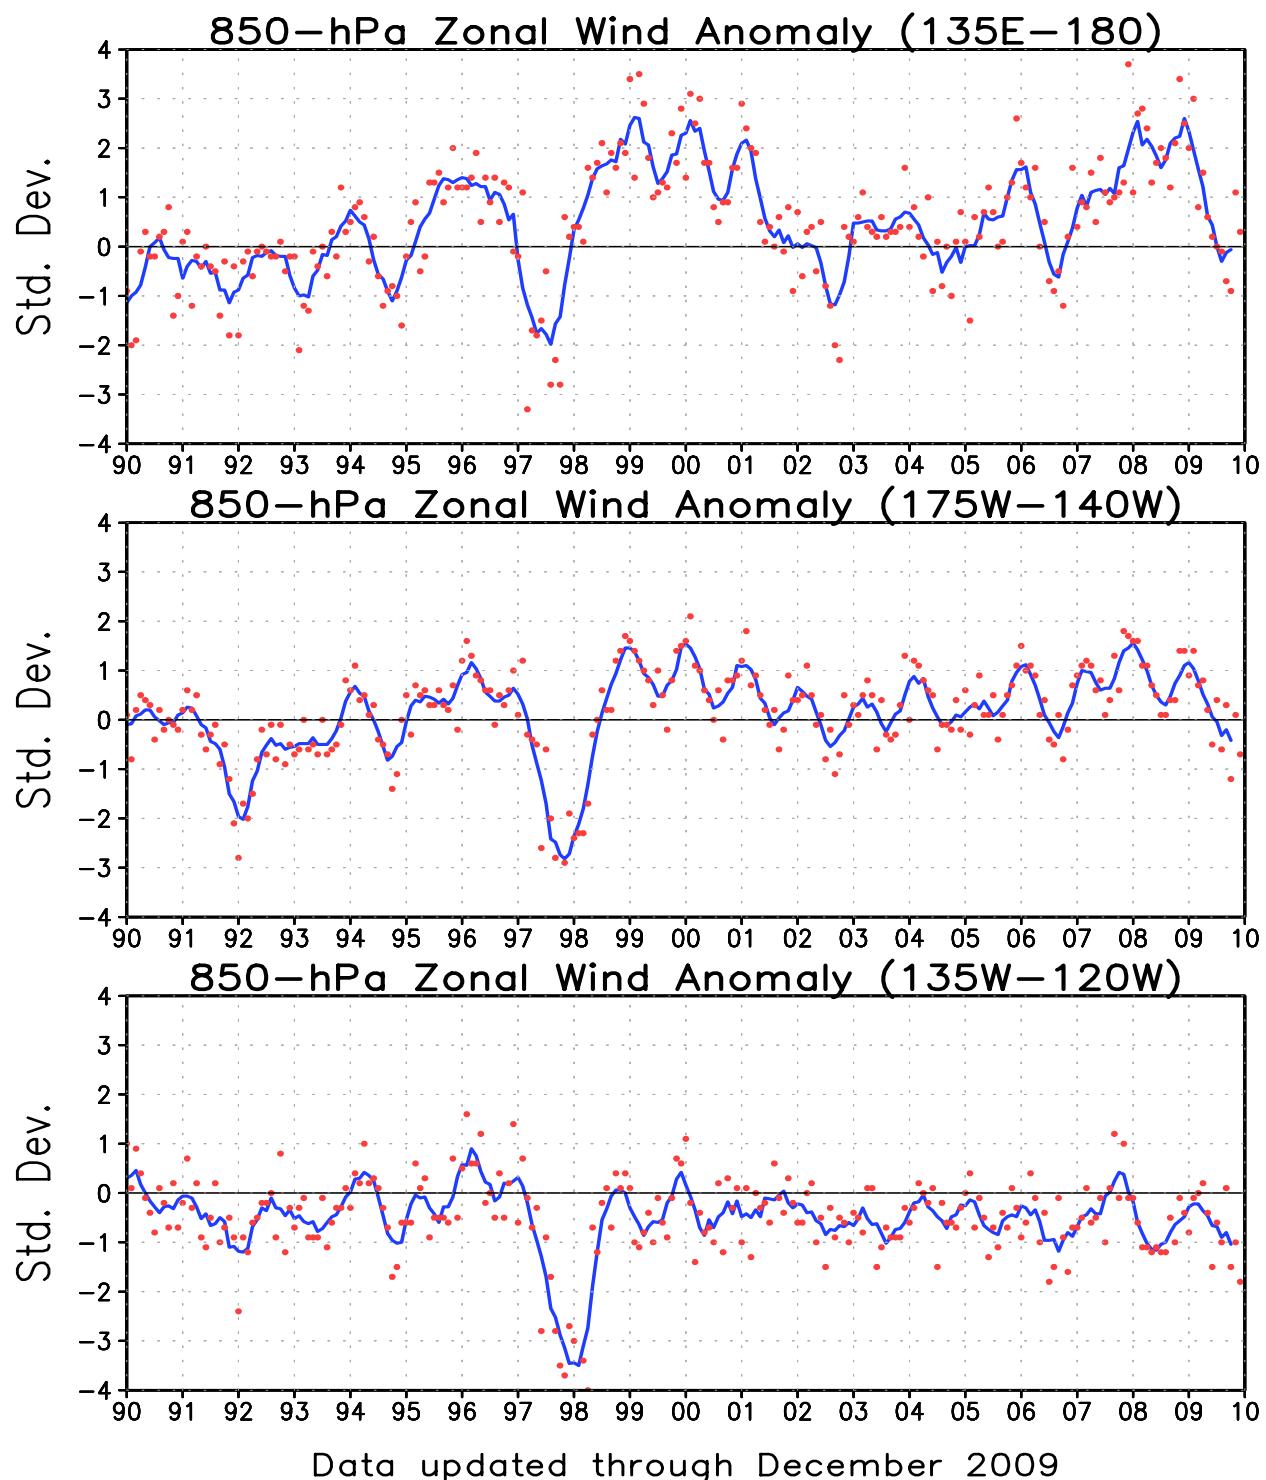

FIGURE T4. Five-month running mean (solid line) and individual monthly mean (dots) of the standardized 850-hPa zonal wind anomaly index in the latitude belt 5N-5S for 135E-180 (top), 175W-140W (middle) and 135W-120W (bottom). Anomalies are departures from the 1979-1995 base period means and are normalized by the mean annual standard deviation. The x-axis labels are centered on January. Positive (negative) values indicate easterly (westerly) anomalies.

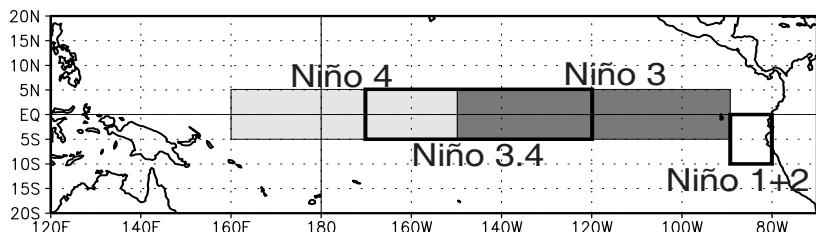

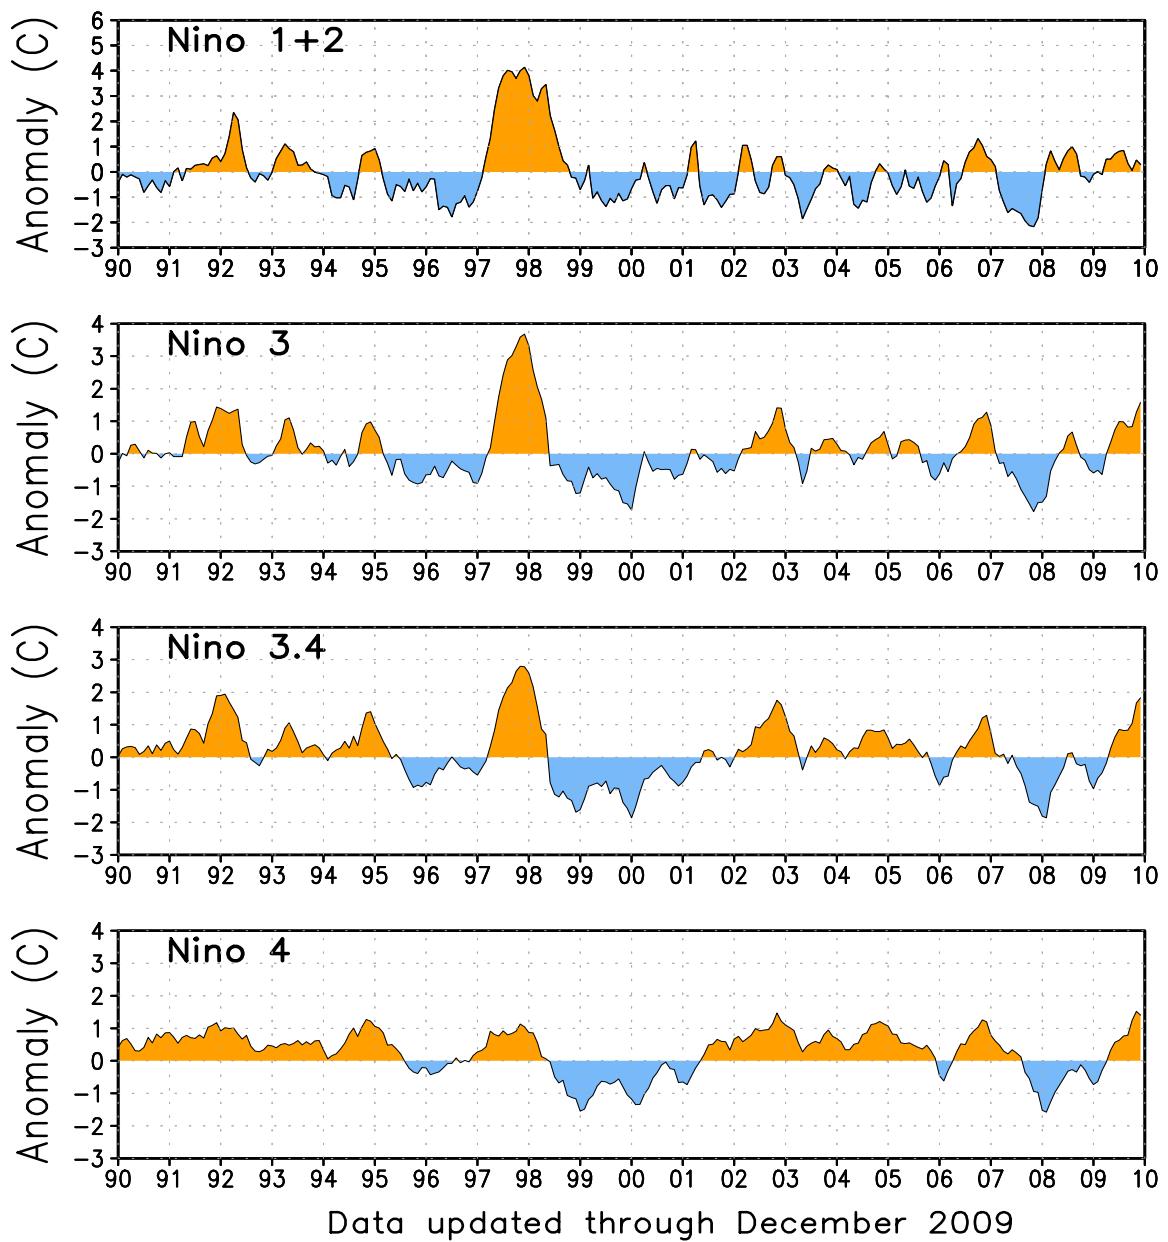

FIGURE T5. Niño region indices, calculated as the area-averaged sea surface temperature anomalies (C) for the specified region. The Niño 1+2 region (top) covers the extreme eastern equatorial Pacific between 0-10S, 90W-80W. The Niño-3 region (2nd from top) spans the eastern equatorial Pacific between 5N-5S, 150W-90W. The Niño 3.4 region (3rd from top) spans the east-central equatorial Pacific between 5N-5S, 170W-120W. The Niño 4 region (bottom) spans the date line and covers the area 5N-5S, 160E-150W. Anomalies are departures from the 1971-2000 base period monthly means (*Smith and Reynolds 1998, J. Climate, 11, 3320-3323*). Monthly values of each index are also displayed in [Table 2](#).

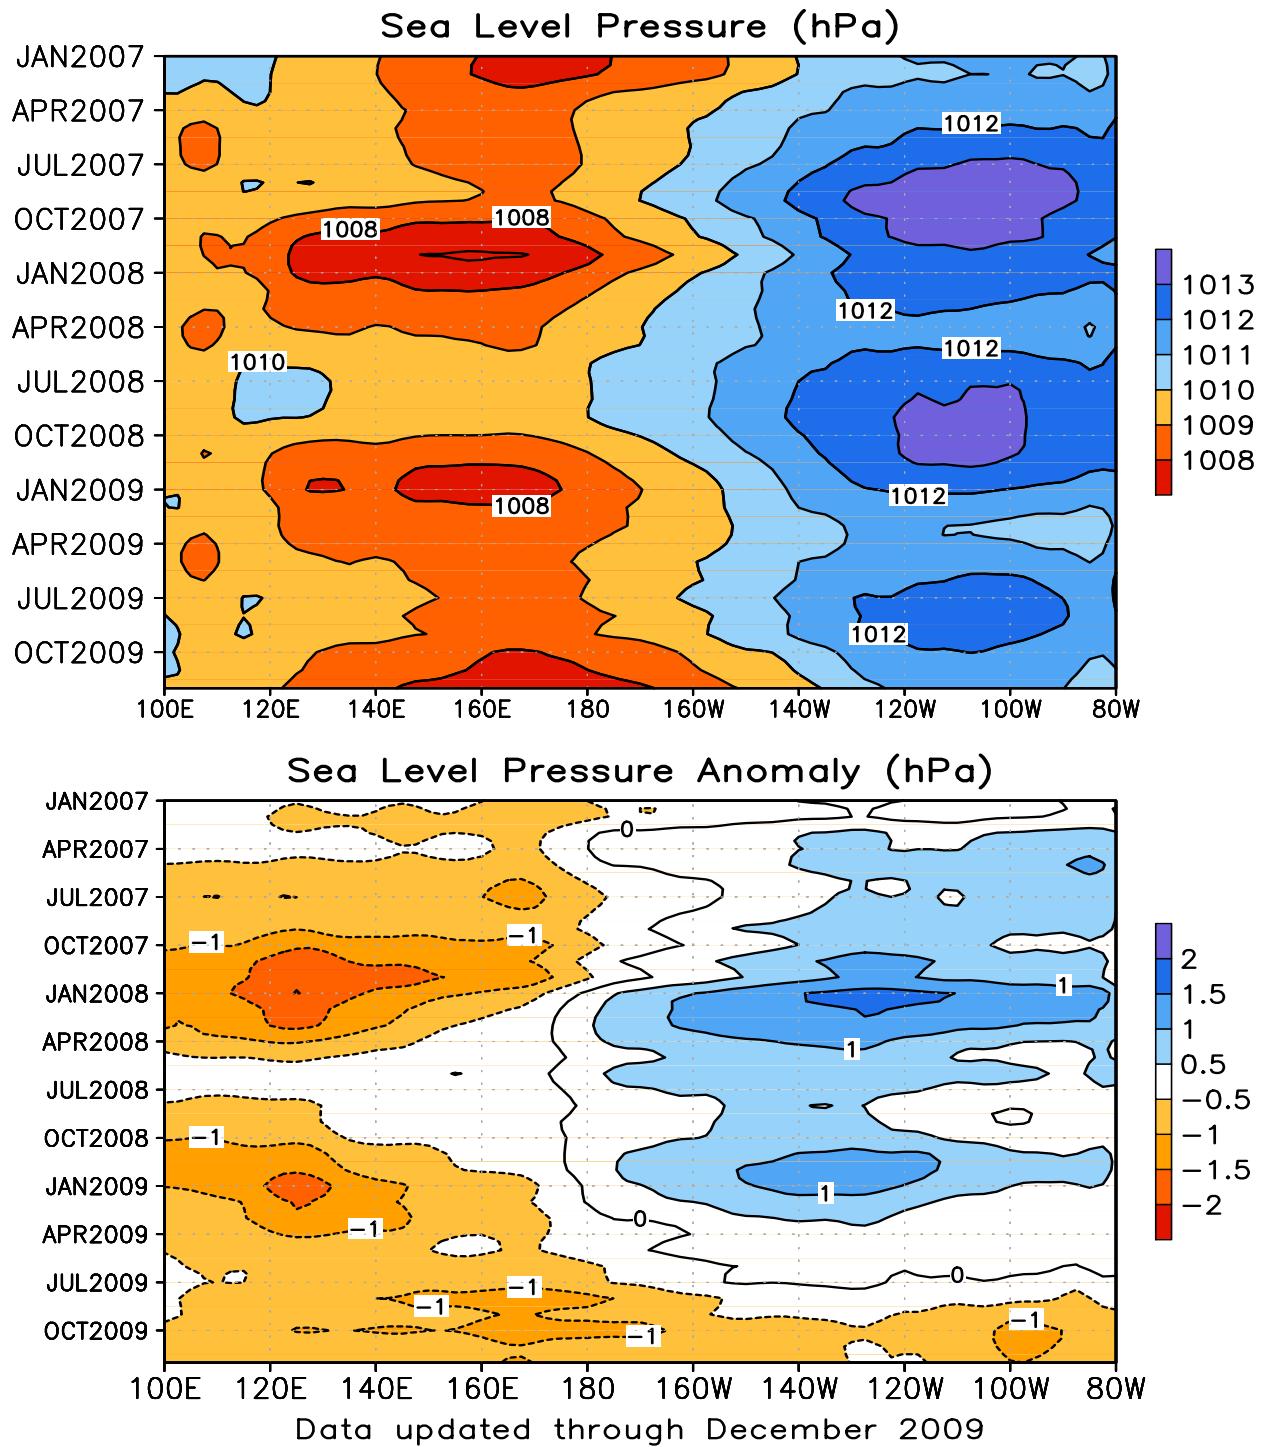

FIGURE T6. Time-longitude section of mean (top) and anomalous (bottom) sea level pressure (SLP) averaged between 5N-5S (CDAS/Reanalysis). Contour interval is 1.0 hPa (top) and 0.5 hPa (bottom). Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1979-1995 base period monthly means. The data are smoothed temporally using a 3-month running average.

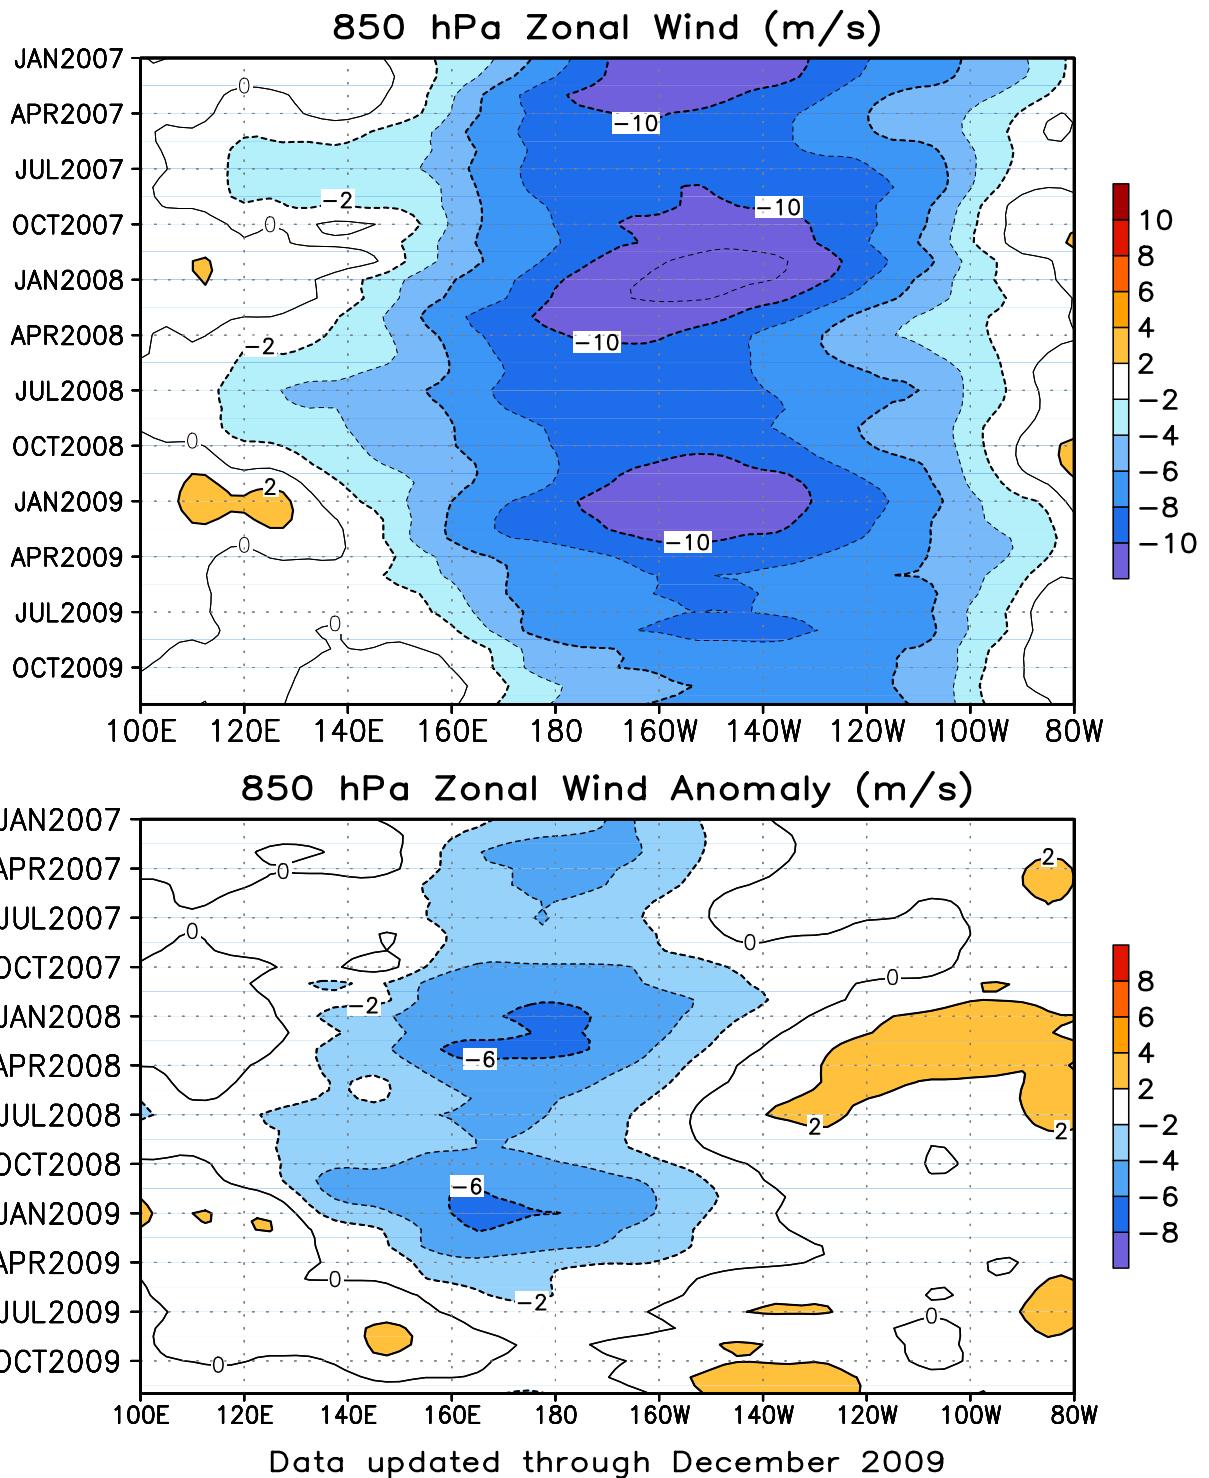

FIGURE T7. Time-longitude section of mean (top) and anomalous (bottom) 850-hPa zonal wind averaged between 5N-5S (CDAS/Reanalysis). Contour interval is 2 ms^{-1} . Blue shading and dashed contours indicate easterlies (top) and easterly anomalies (bottom). Anomalies are departures from the 1979-1995 base period monthly means. The data are smoothed temporally using a 3-month running average.

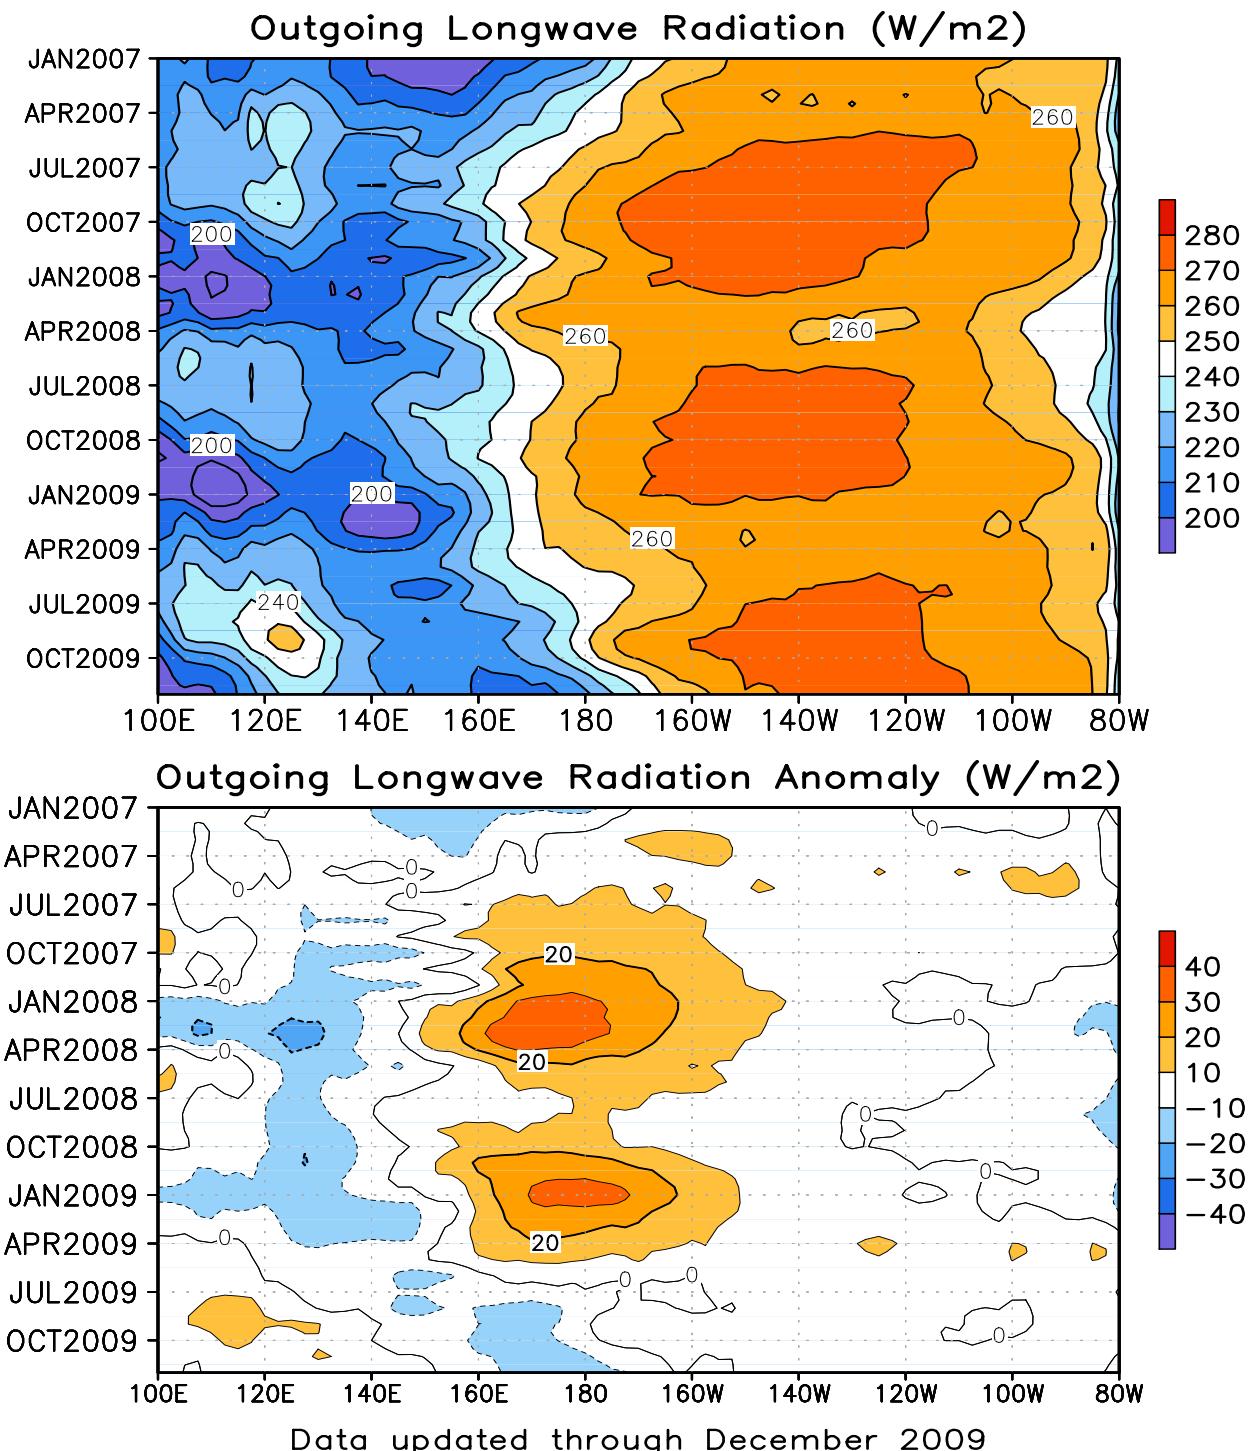

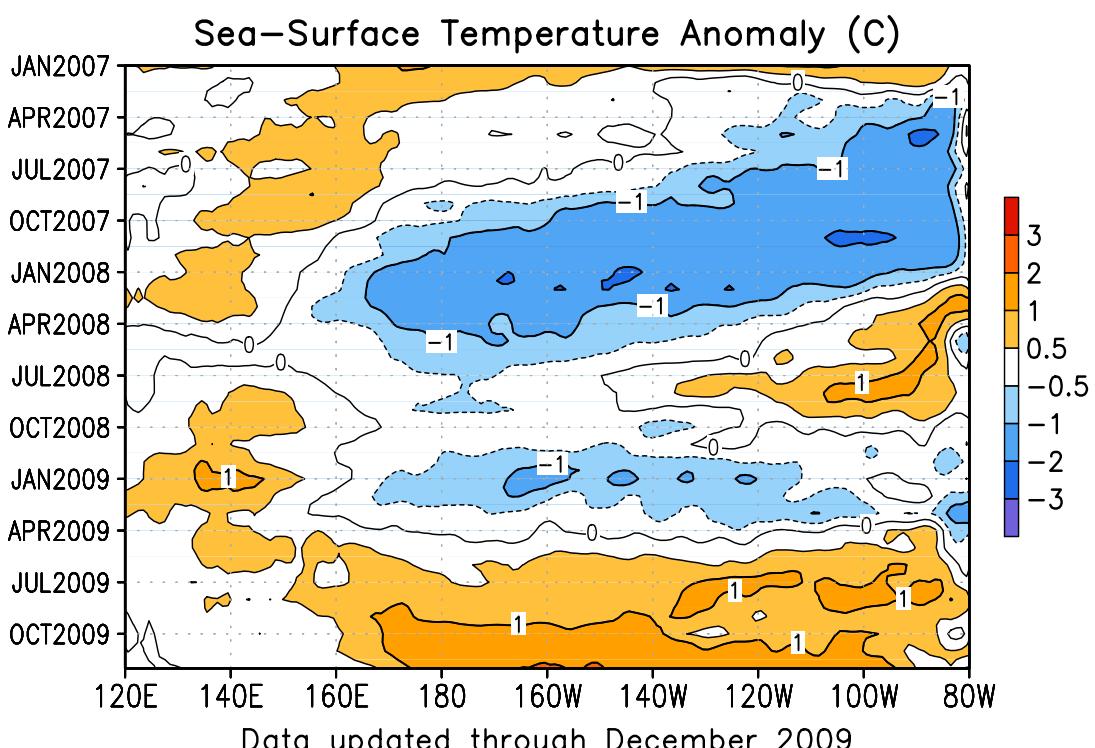

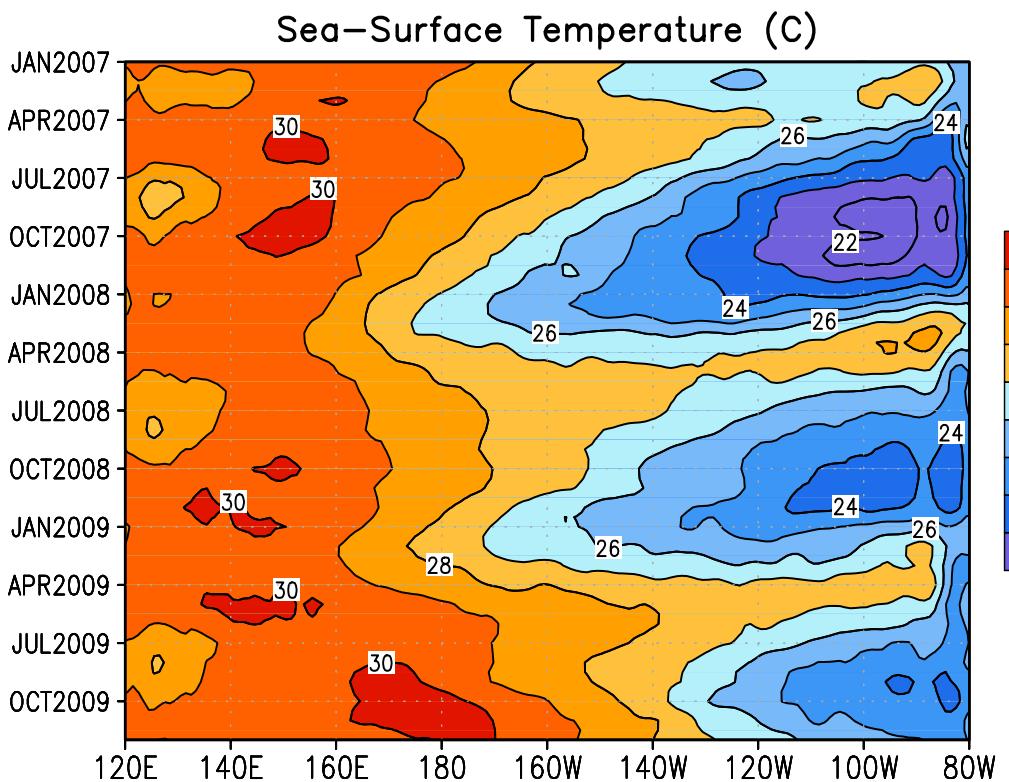

FIGURE T8. Time-longitude section of mean (top) and anomalous (bottom) outgoing longwave radiation (OLR) averaged between 5N-5S. Contour interval is 10 Wm⁻². Dashed contours in bottom panel indicate negative OLR anomalies. Anomalies are departures from the 1979-1995 base period monthly means. The data are smoothed temporally using a 3-month running average.

Data updated through December 2009

FIGURE T9. Time-longitude section of monthly mean (top) and anomalous (bottom) sea surface temperature (SST) averaged between 5N-5S. Contour interval is 1C (top) and 0.5C (bottom). Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1971-2000 base period means (Smith and Reynolds 1998, *J. Climate*, **11**, 3320-3323).

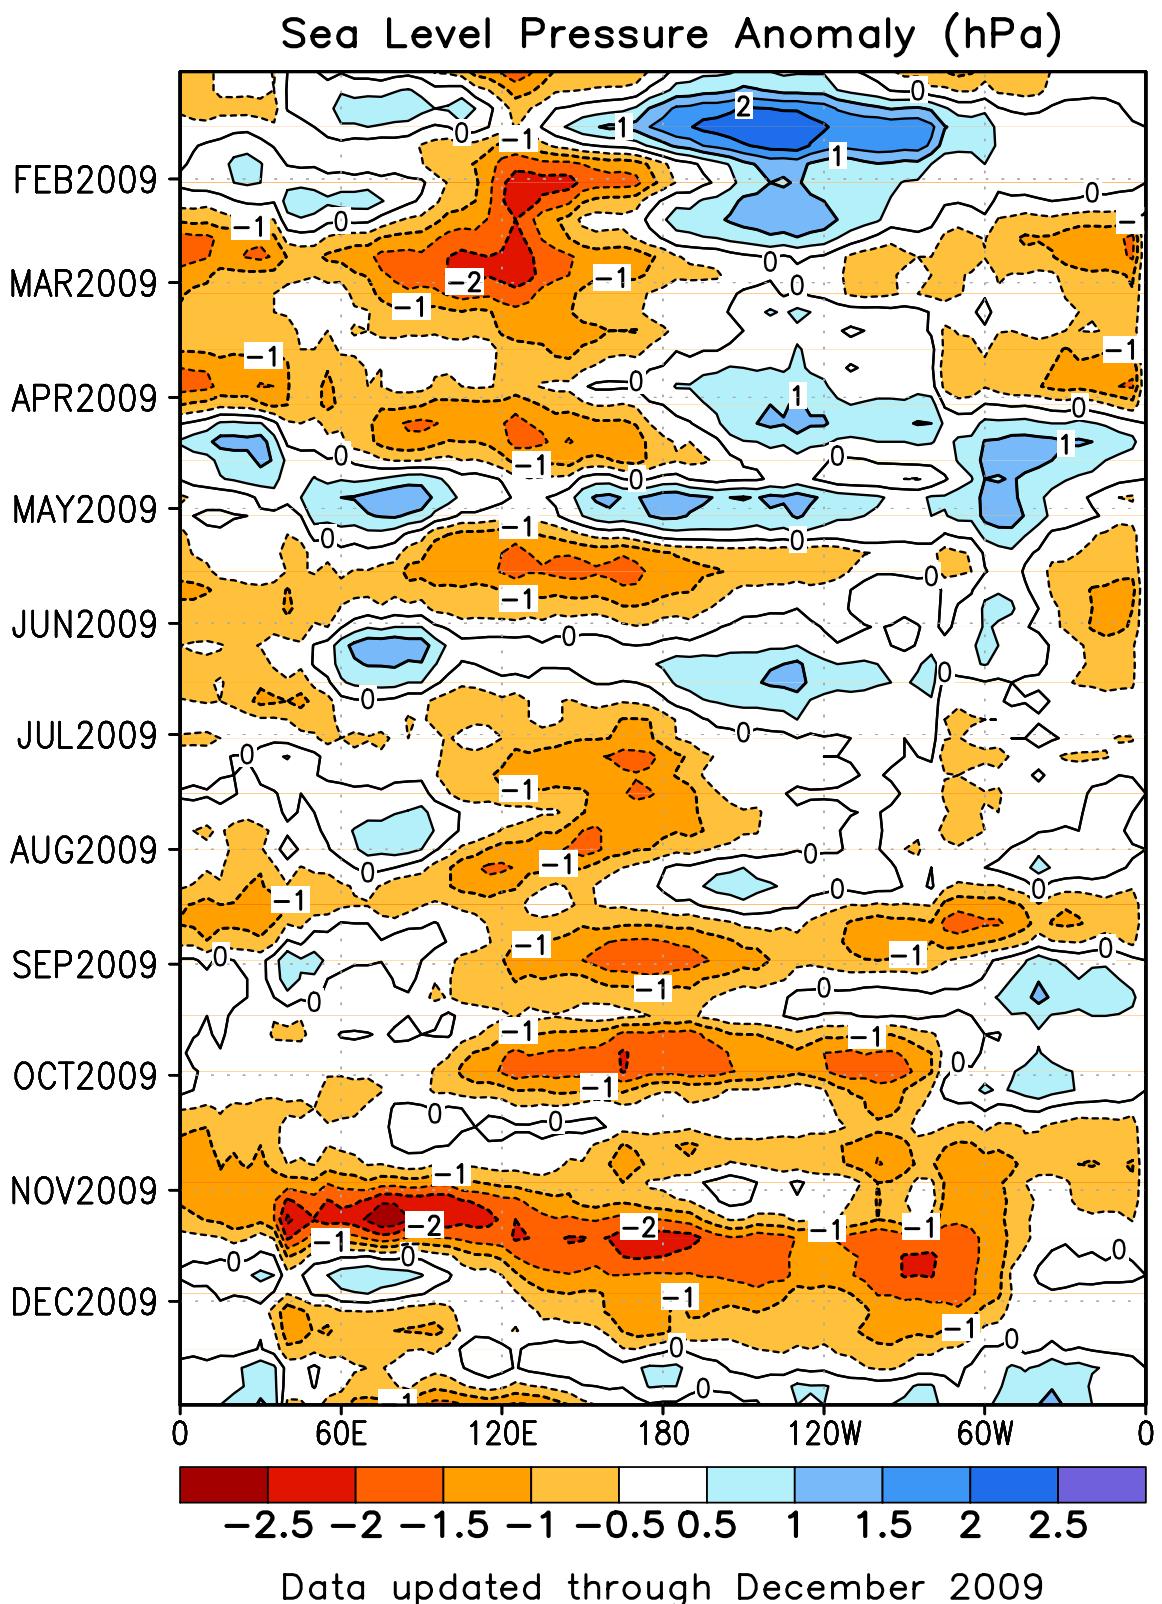

FIGURE T10. Time-longitude section of anomalous sea level pressure (hPa) averaged between 5N-5S (CDAS/Reranysis). Contour interval is 1 hPa. Dashed contours indicate negative anomalies. Anomalies are departures from the 1979-1995 base period pentad means. The data are smoothed temporally using a 3-point running average.

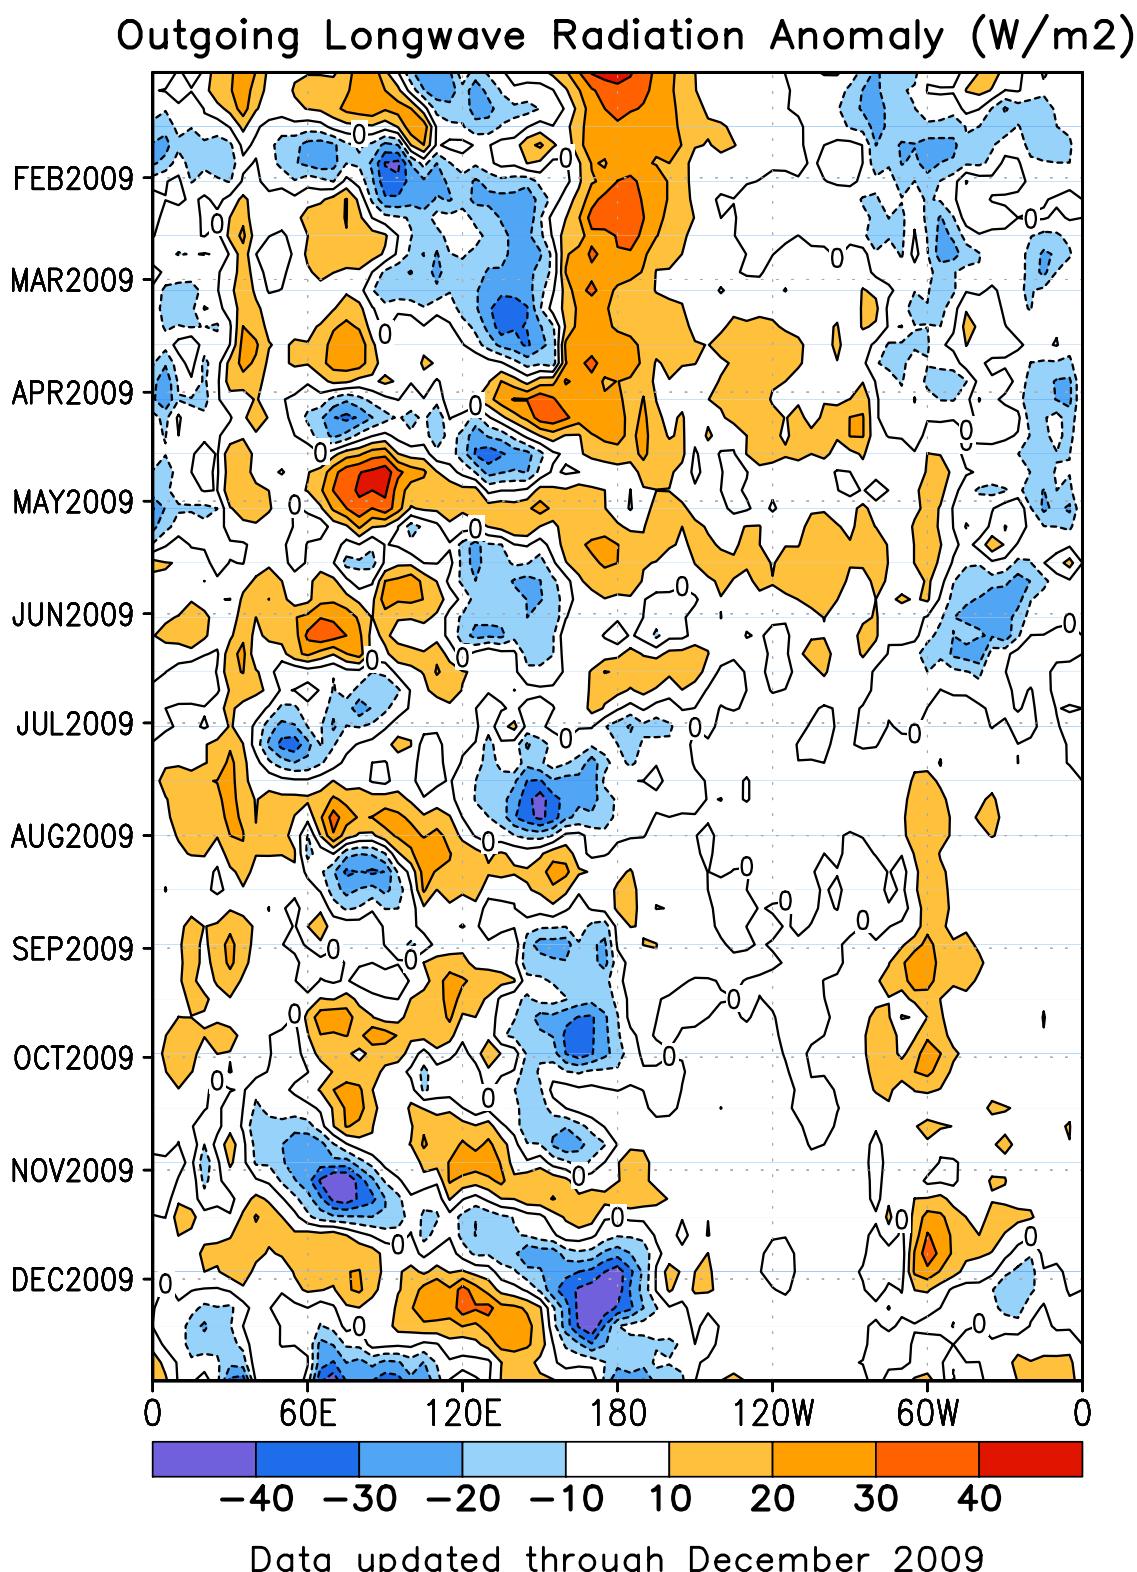

FIGURE T11. Time-longitude section of anomalous outgoing longwave radiation averaged between 5N-5S. Contour interval is 15 Wm⁻². Dashed contours indicate negative anomalies. Anomalies are departures from the 1979-1995 base period pentad means. The data are smoothed temporally using a 3-point running average.

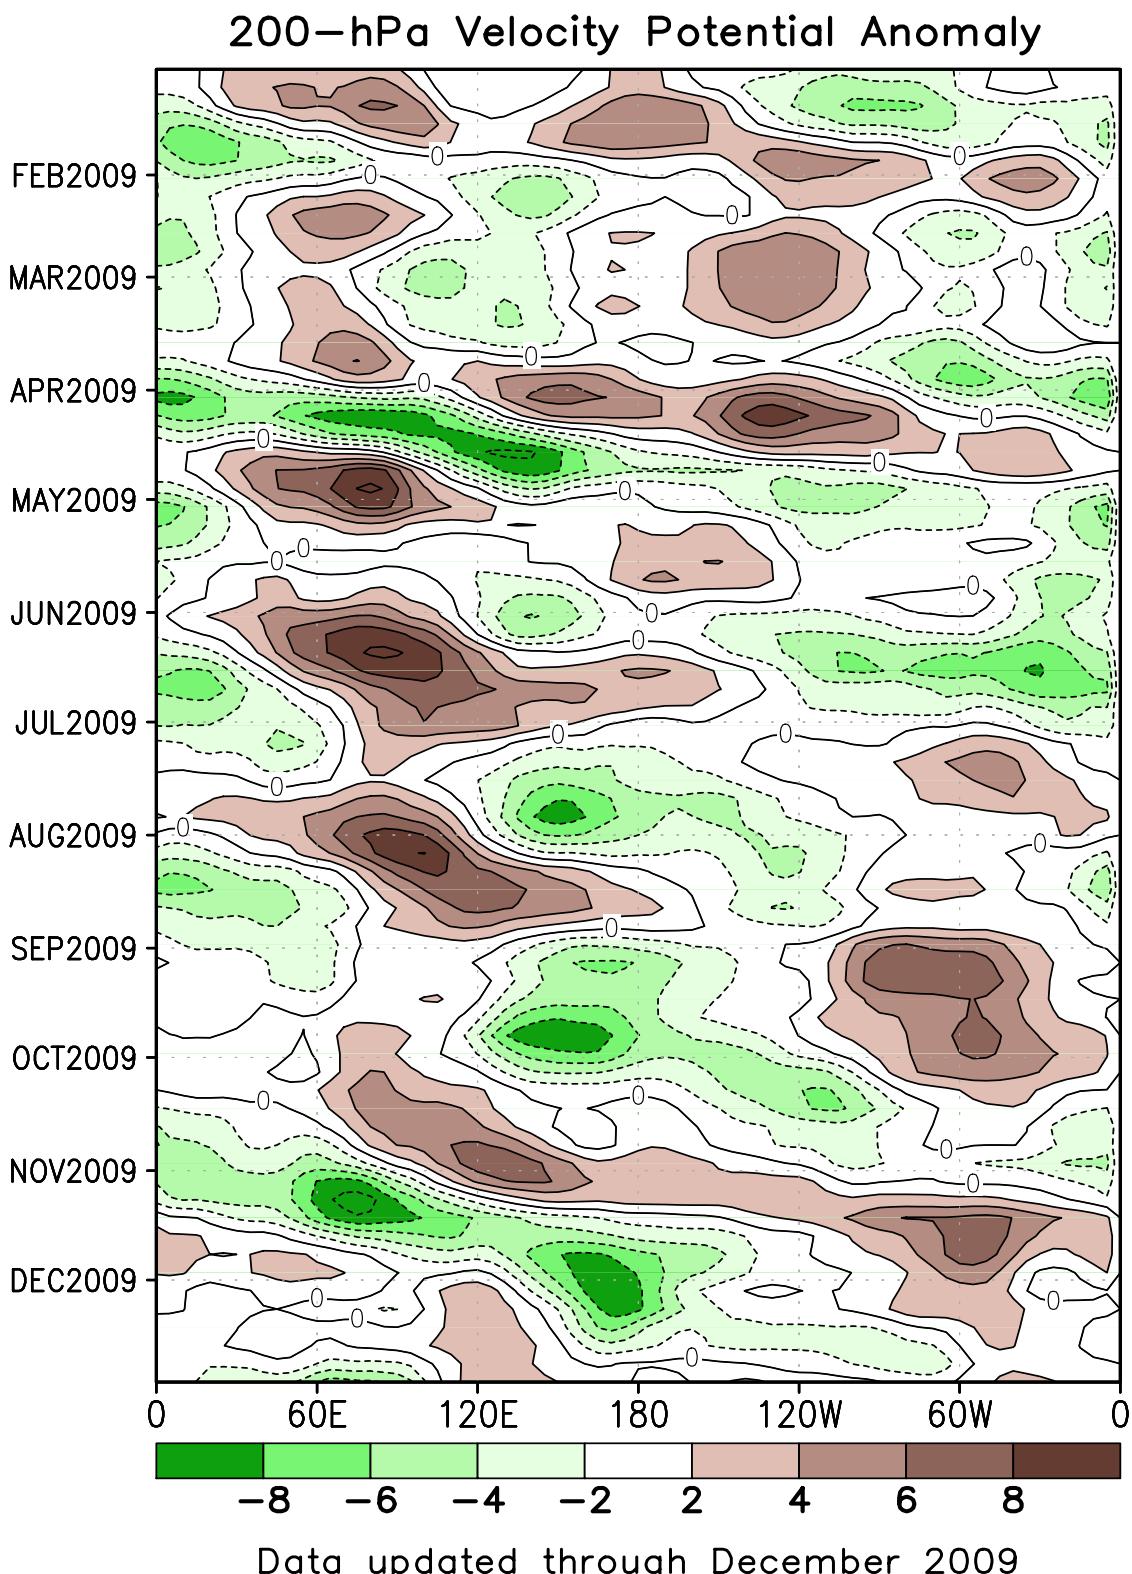

FIGURE T12. Time-longitude section of anomalous 200-hPa velocity potential averaged between 5N-5S (CDAS/Re-analysis). Contour interval is $3 \times 10^6 \text{ m}^2 \text{s}^{-1}$. Dashed contours indicate negative anomalies. Anomalies are departures from the 1979-1995 base period pentad means. The data are smoothed temporally using a 3-point running average.

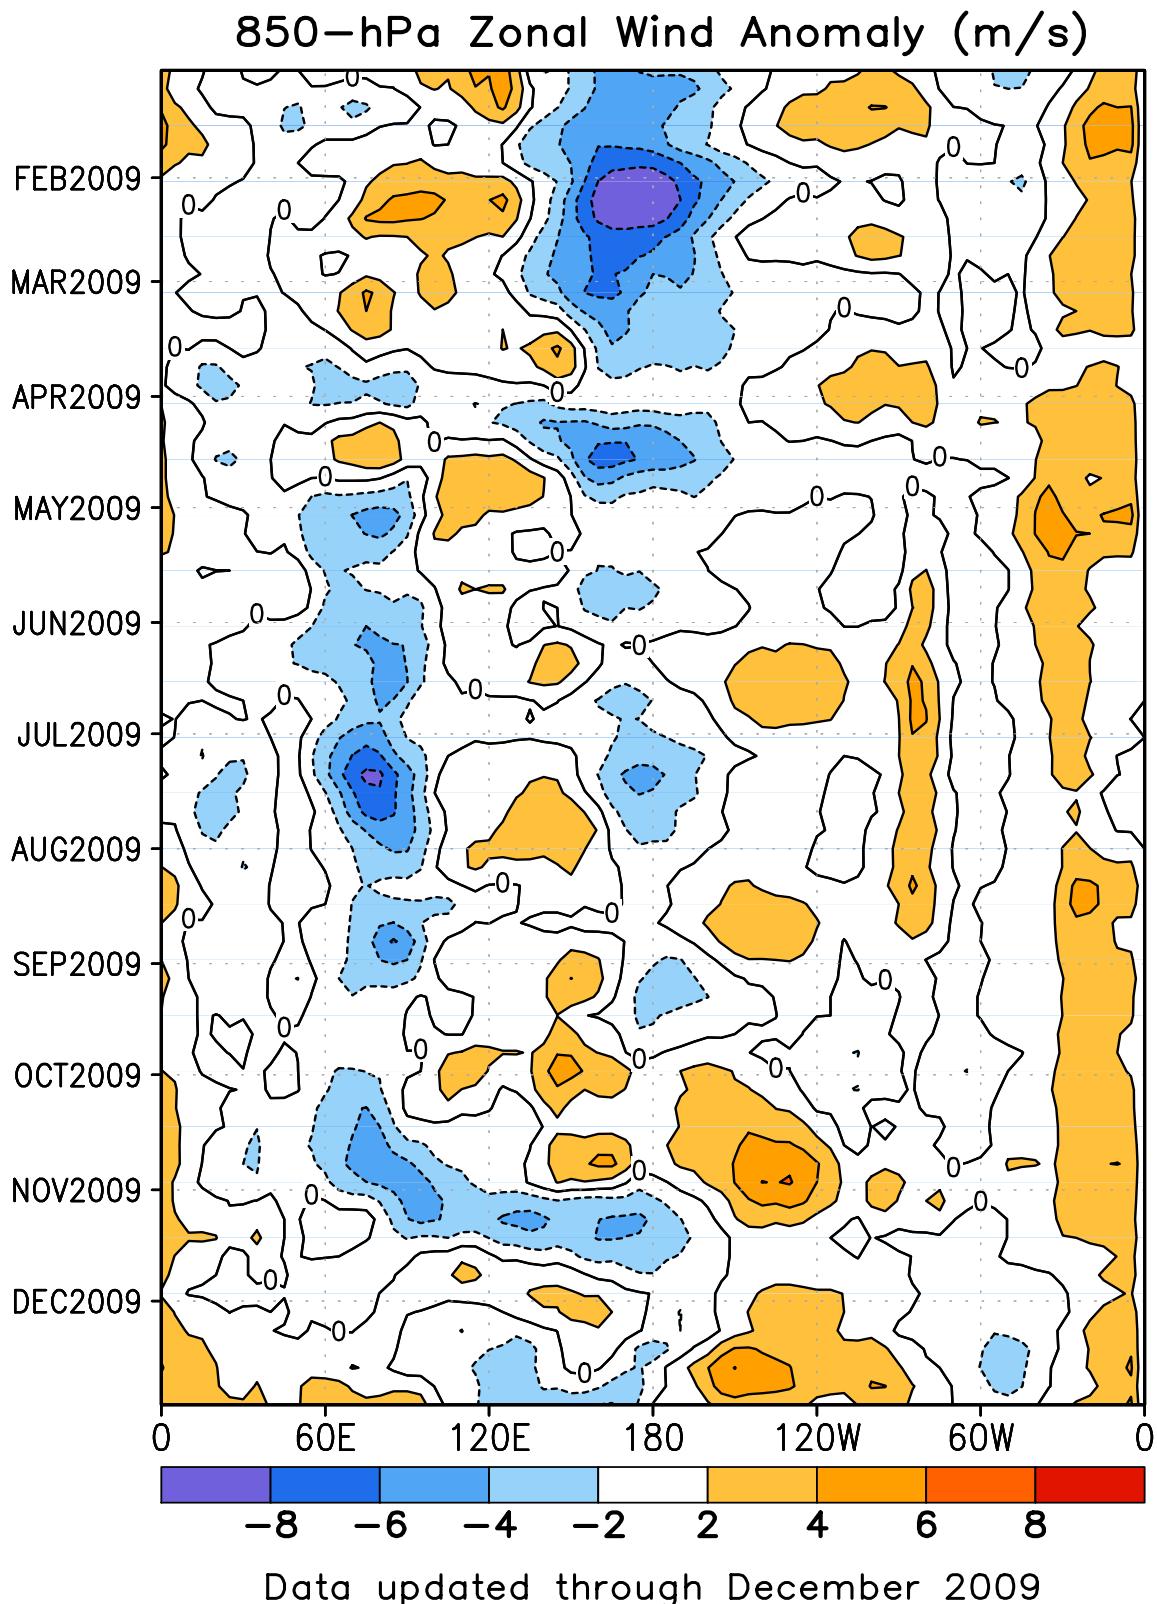

FIGURE T13. Time-longitude section of anomalous 850-hPa zonal wind averaged between 5N-5S (CDAS/Reanalysis). Contour interval is 2 ms^{-1} . Dashed contours indicate negative anomalies. Anomalies are departures from the 1979-1995 base period pentad means. The data are smoothed temporally by using a 3-point running average.

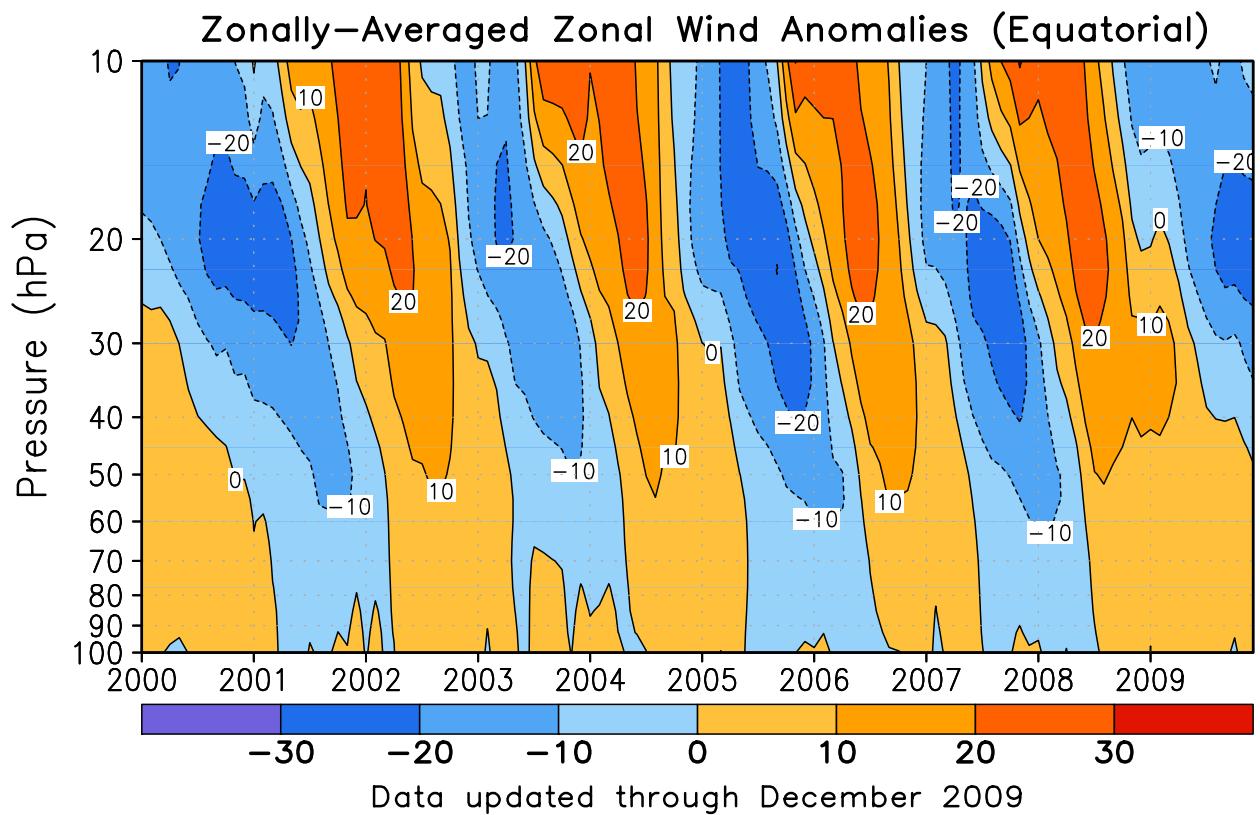

FIGURE T14. Equatorial time-height section of anomalous zonally-averaged zonal wind (m s^{-1}) (CDAS/Reanalysis). Contour interval is 10 ms^{-1} . Anomalies are departures from the 1979-1995 base period monthly means.

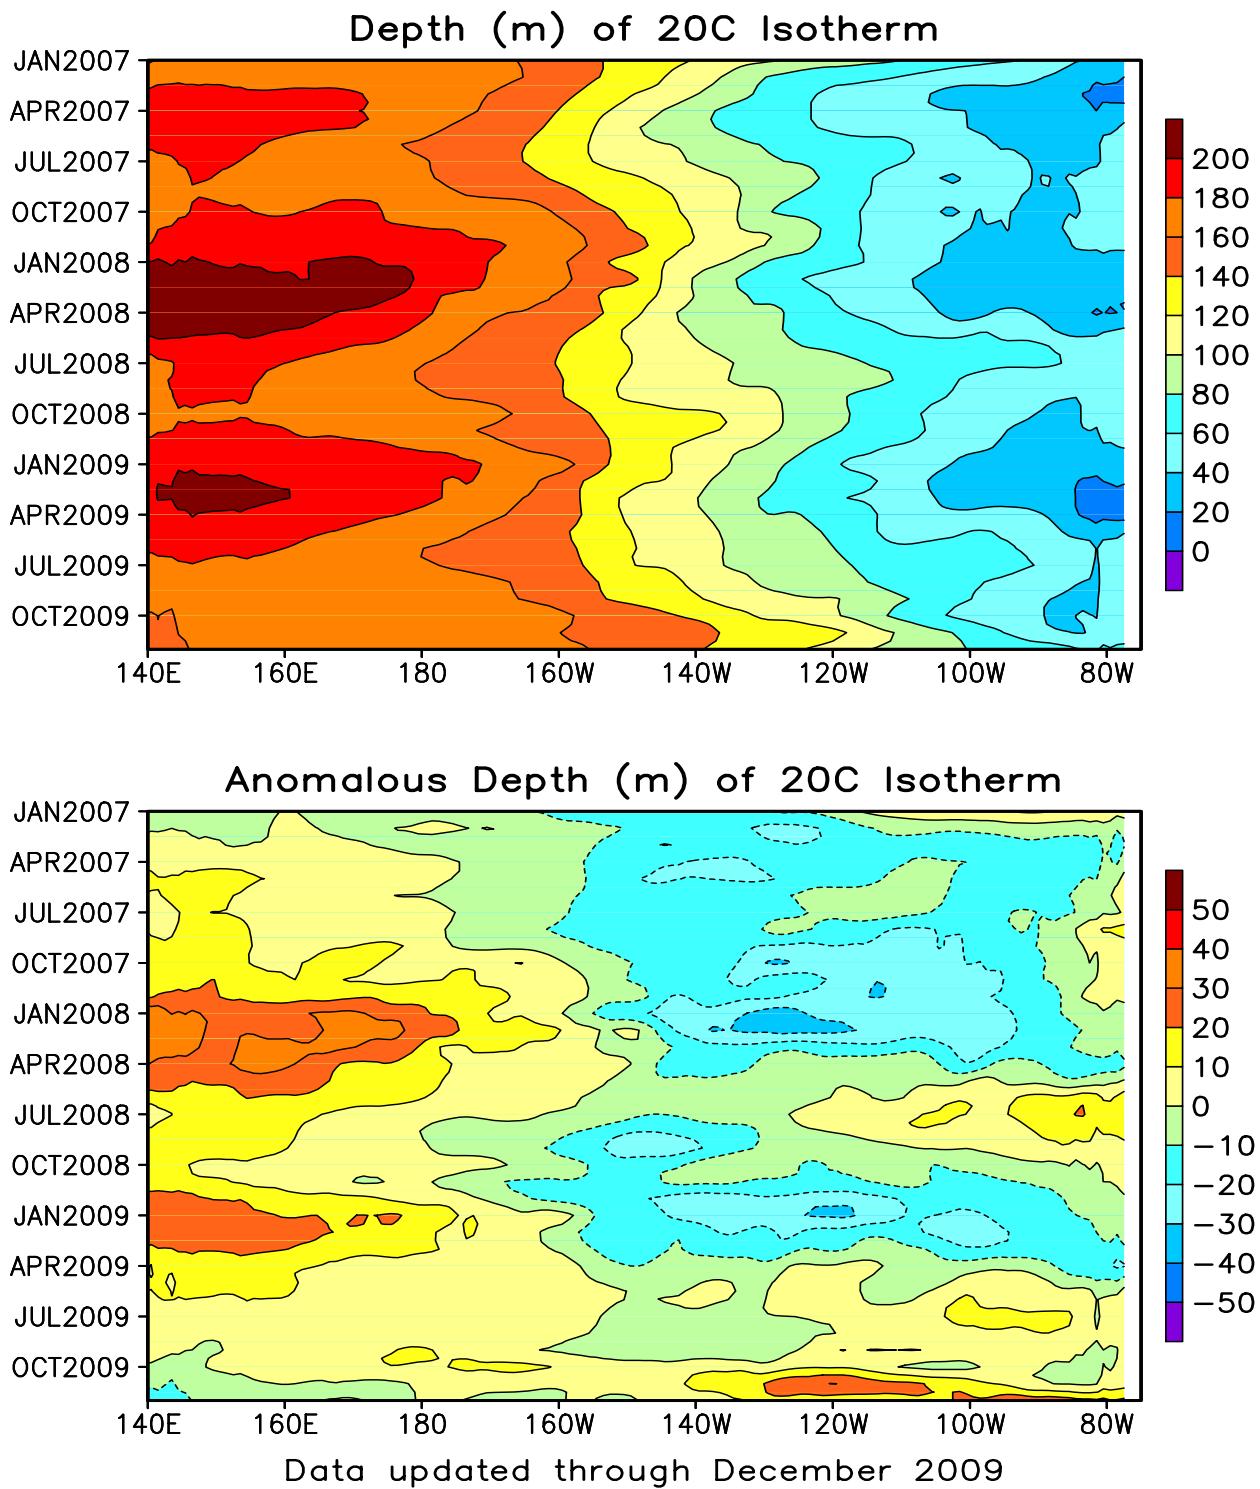

FIGURE T15. Mean (top) and anomalous (bottom) depth of the 20C isotherm averaged between 5N-5S in the Pacific Ocean. Data are derived from the NCEP's global ocean data assimilation system which assimilates oceanic observations into an oceanic GCM (Behringer, D. W., and Y. Xue, 2004: Evaluation of the global ocean data assimilation system at NCEP: The Pacific Ocean. AMS 84th Annual Meeting, Seattle, Washington, 11-15). The contour interval is 10 m. Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1982-2004 base period means.

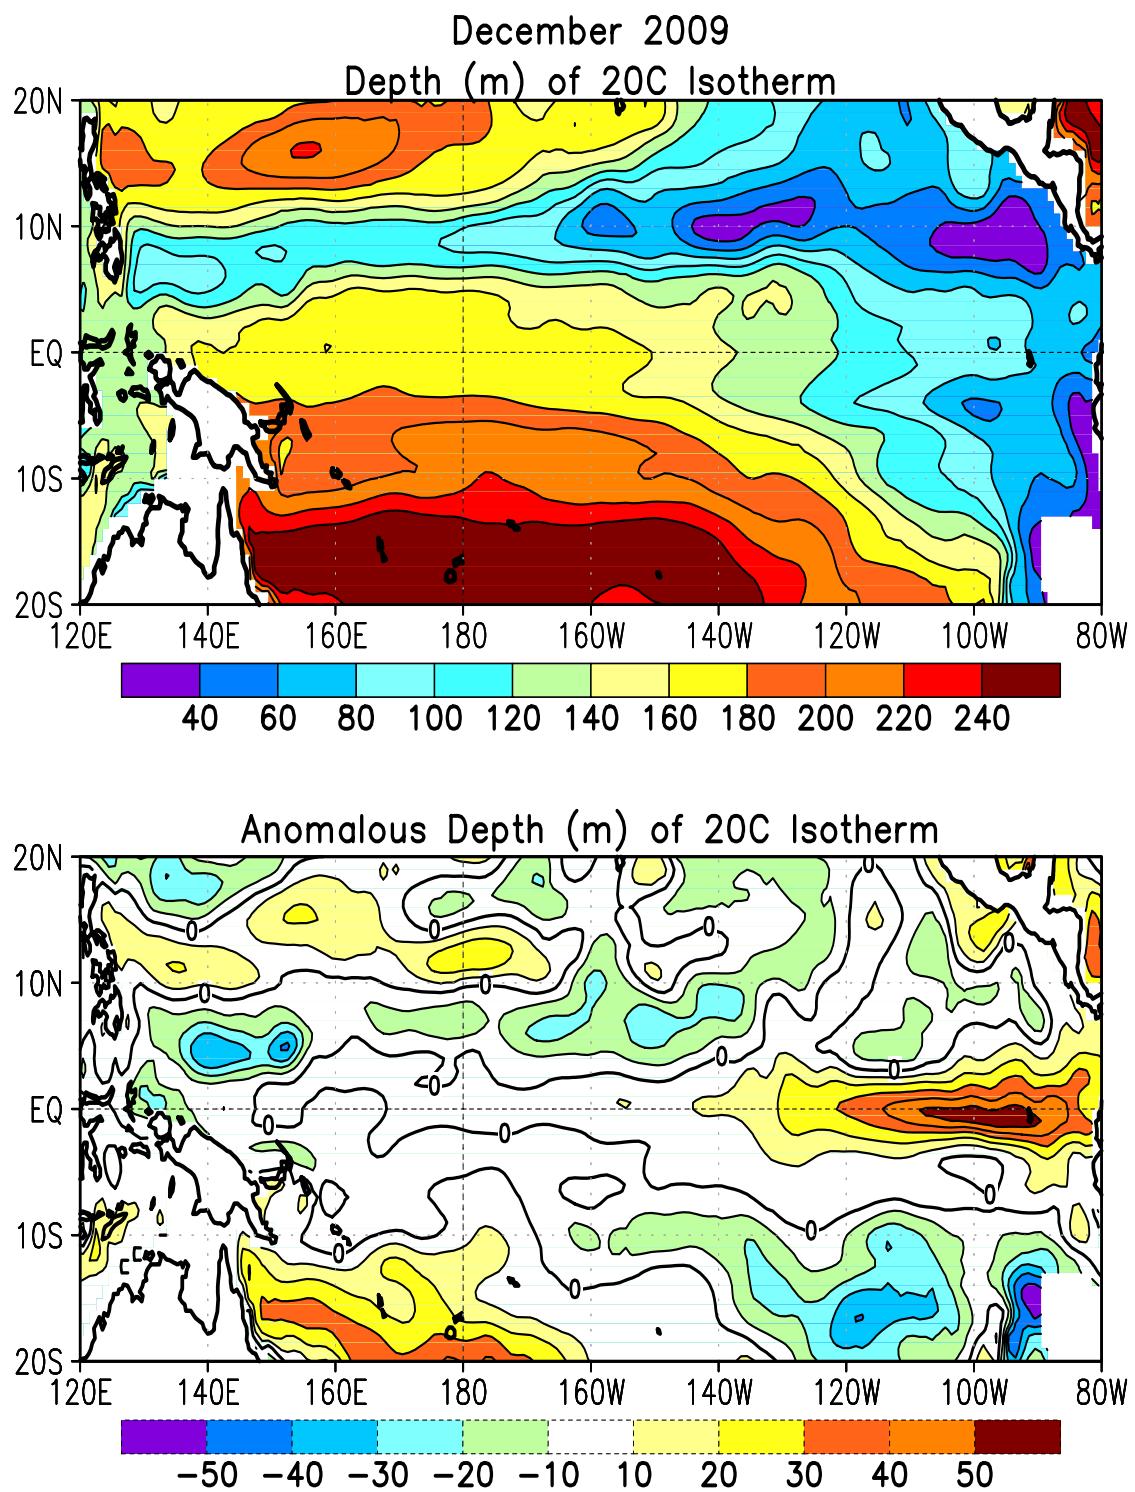

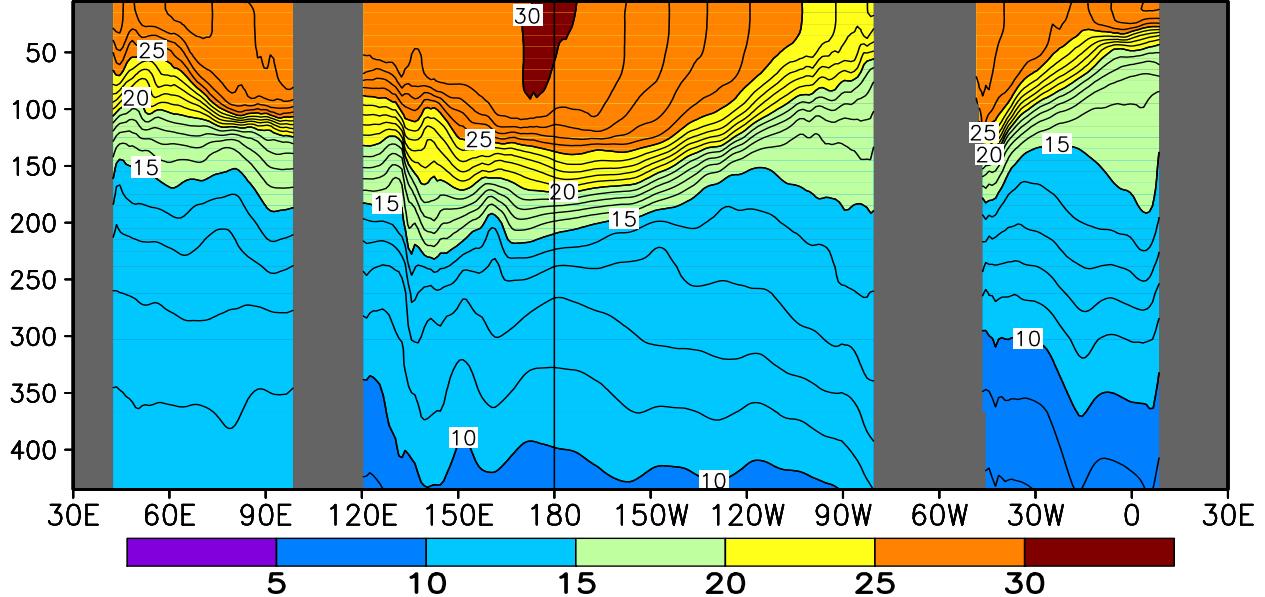

FIGURE T16. Mean (top) and anomalous (bottom) depth of the 20°C isotherm for DEC 2009. Contour interval is 40 m (top) and 10 m (bottom). Dashed contours in bottom panel indicate negative anomalies. Data are derived from the NCEP's global ocean data assimilation system version 2 which assimilates oceanic observations into an oceanic GCM (Xue, Y. and Behringer, D.W., 2006: Operational global ocean data assimilation system at NCEP, to be submitted to BAMS). Anomalies are departures from the 1982–2004 base period means.

December 2009: Depth–Longitude Section
Equatorial Ocean Temperatures (C)

Equatorial Ocean Temperature Anomalies (C)

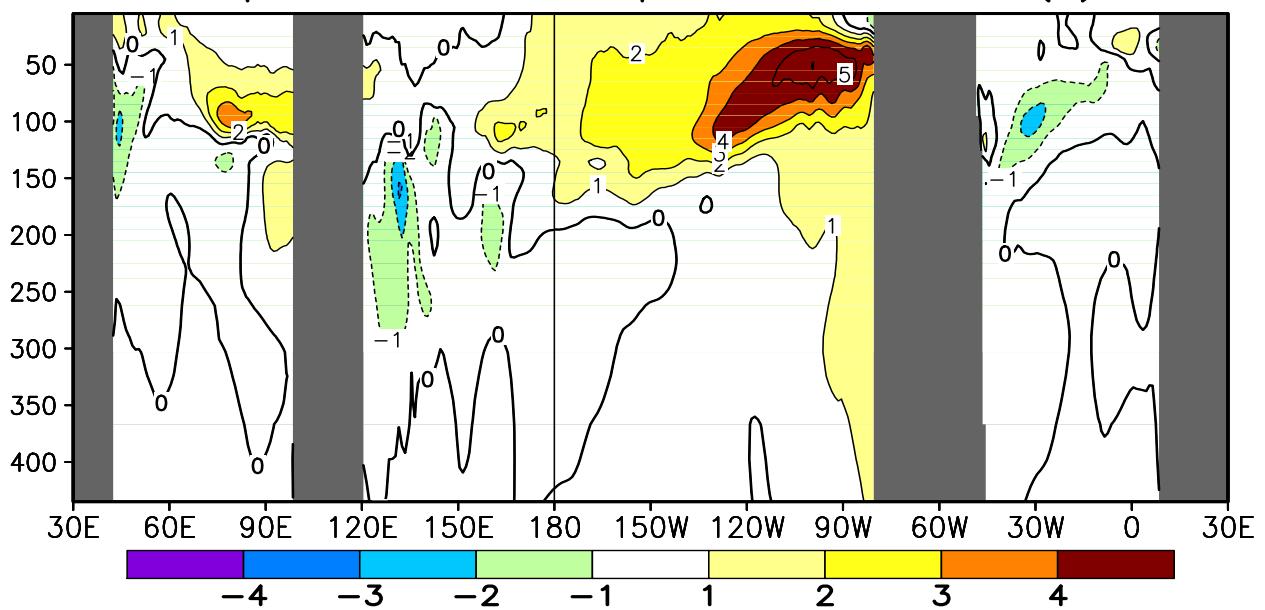

FIGURE T17. Equatorial depth-longitude section of ocean temperature (top) and ocean temperature anomalies (bottom) for DEC 2009. Contour interval is 1°C. Dashed contours in bottom panel indicate negative anomalies. Data are derived from the NCEP's global ocean data assimilation system version 2 which assimilates oceanic observations into an oceanic GCM (Xue, Y. and Behringer, D.W., 2006: Operational global ocean data assimilation system at NCEP, to be submitted to BAMS). Anomalies are departures from the 1982–2004 base period means.

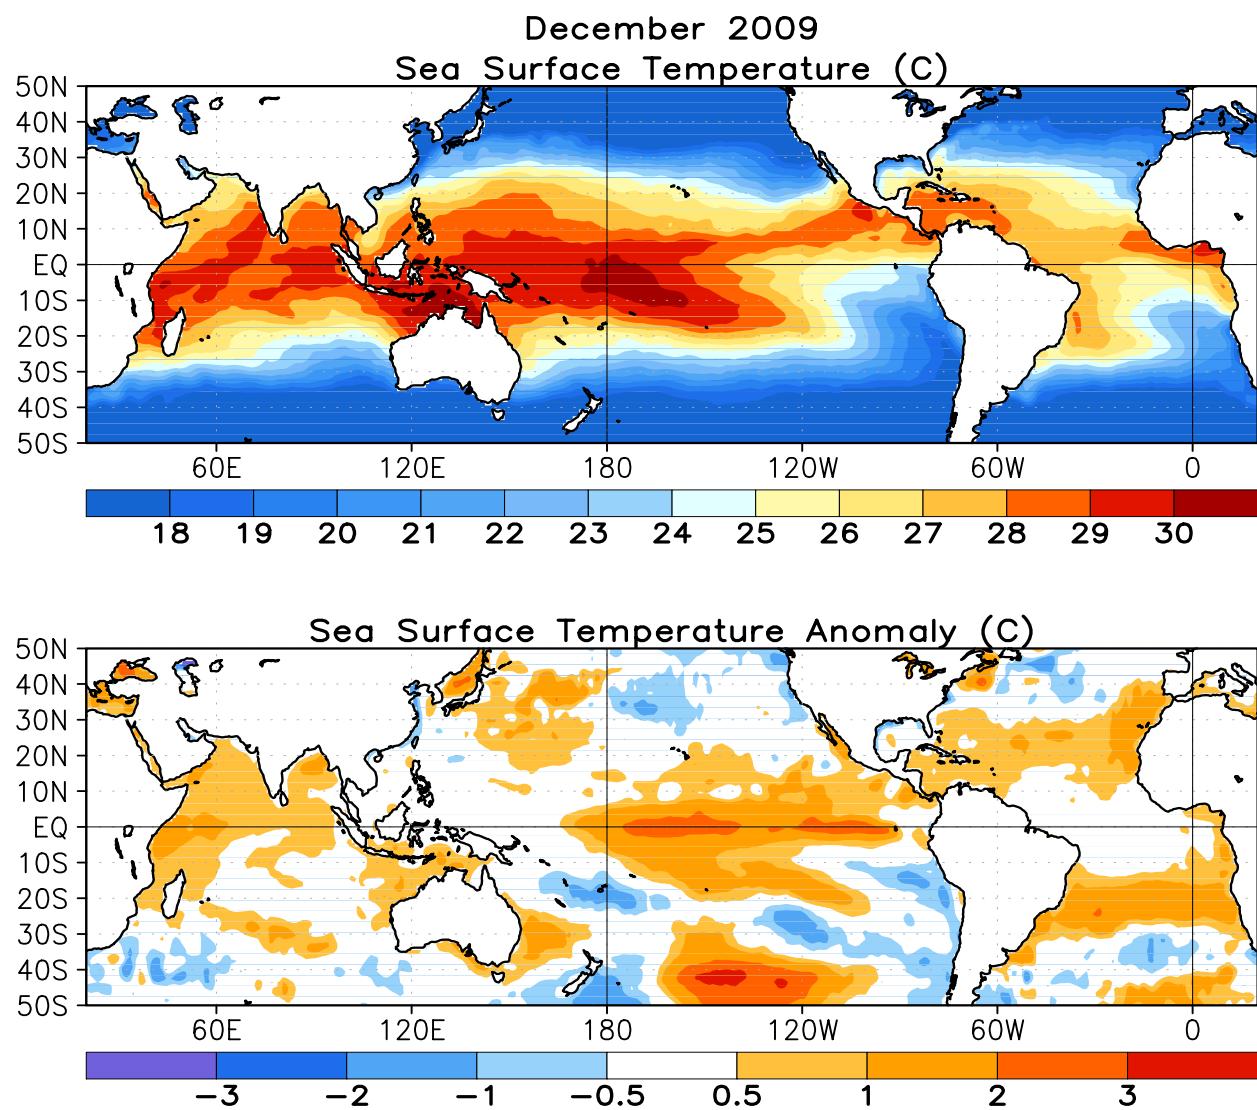

FIGURE T18. Mean (top) and anomalous (bottom) sea surface temperature (SST). Anomalies are departures from the 1971-2000 base period monthly means (Smith and Reynolds 1998, *J. Climate*, **11**, 3320-3323).

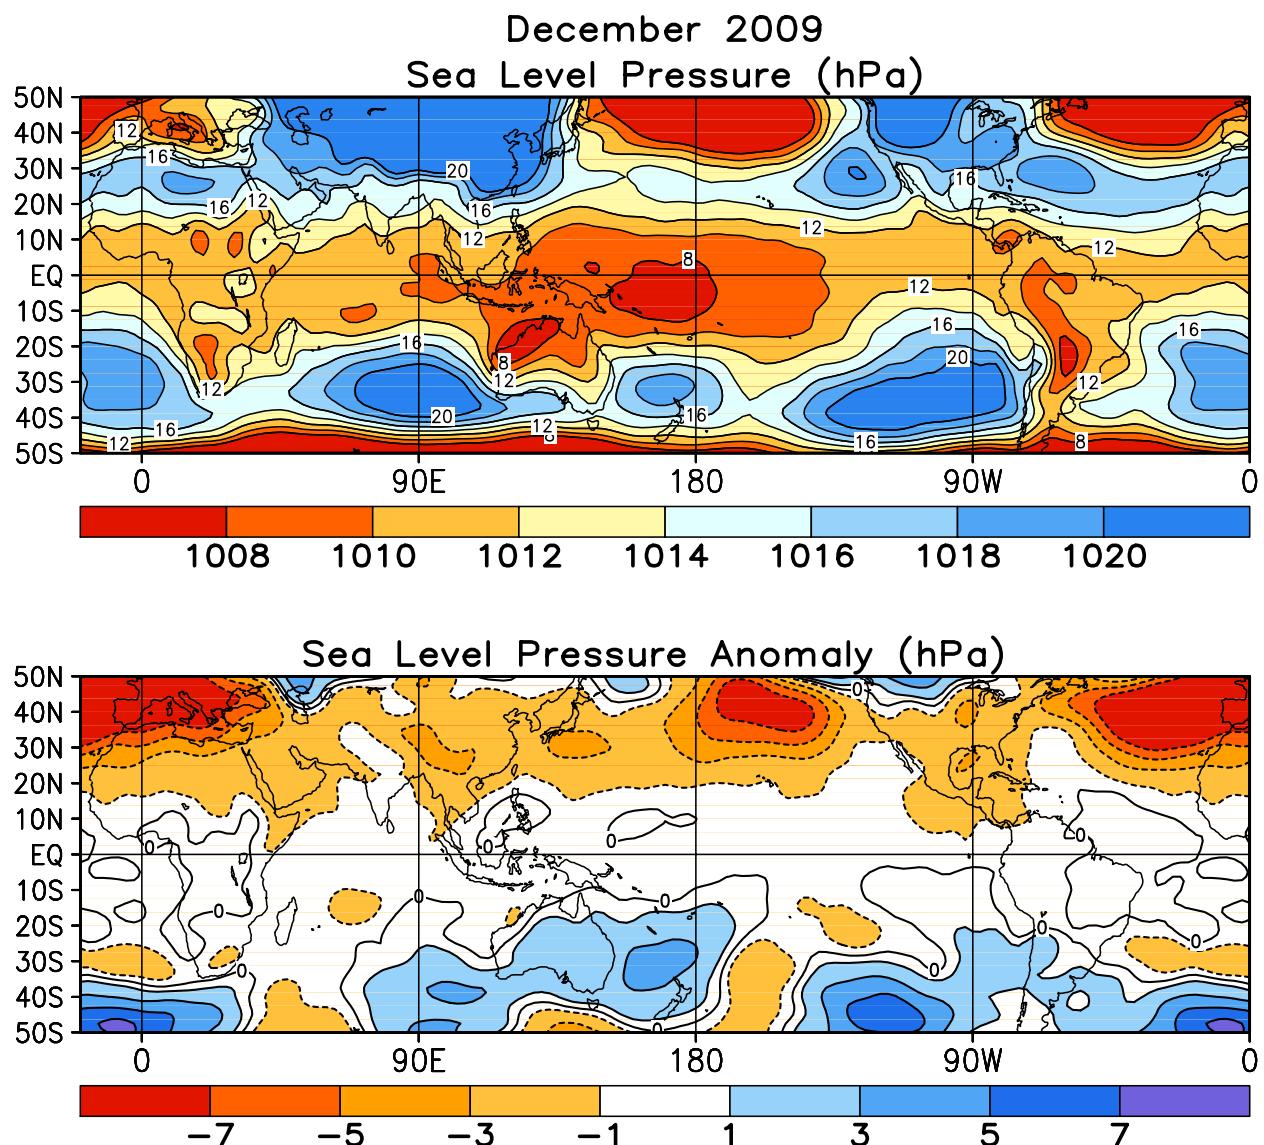

FIGURE T19. Mean (top) and anomalous (bottom) sea level pressure (SLP) (CDAS/Reanalysis). In top panel, 1000 hPa has been subtracted from contour labels, contour interval is 2 hPa, and values below 1000 hPa are indicated by dashed contours. In bottom panel, anomaly contour interval is 1 hPa and negative anomalies are indicated by dashed contours. Anomalies are departures from the 1979-1995 base period monthly means.

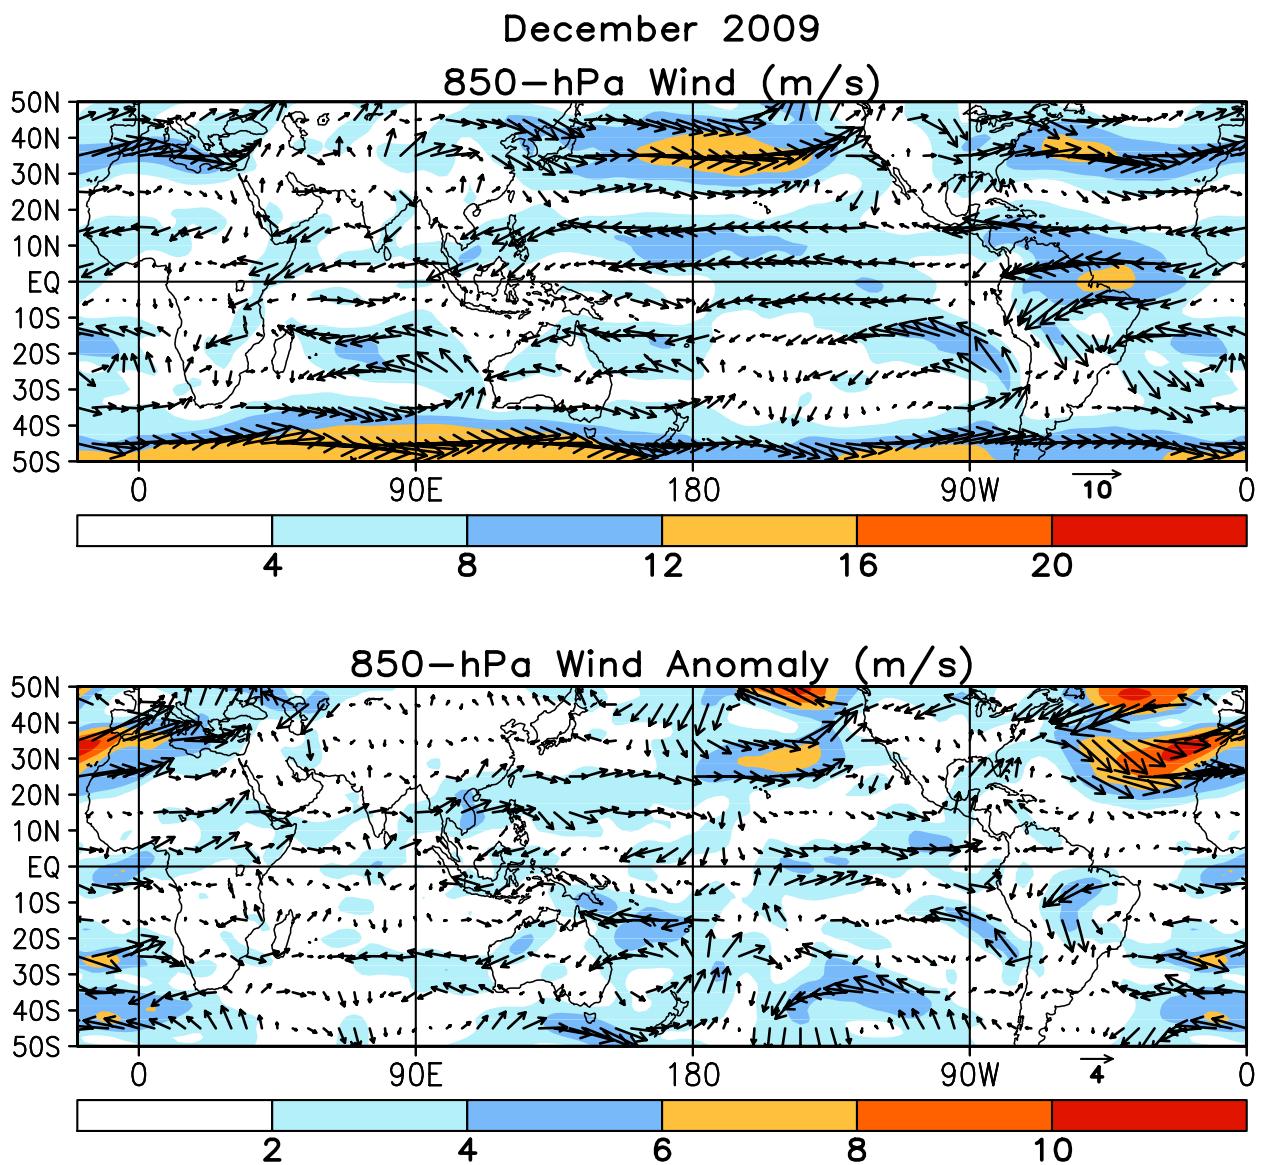

FIGURE T20. Mean (top) and anomalous (bottom) 850-hPa vector wind (CDAS/Reanalysis) for DEC 2009. Contour interval for isotachs is 4 ms^{-1} (top) and 2 ms^{-1} (bottom). Anomalies are departures from the 1979–95 base period monthly means.

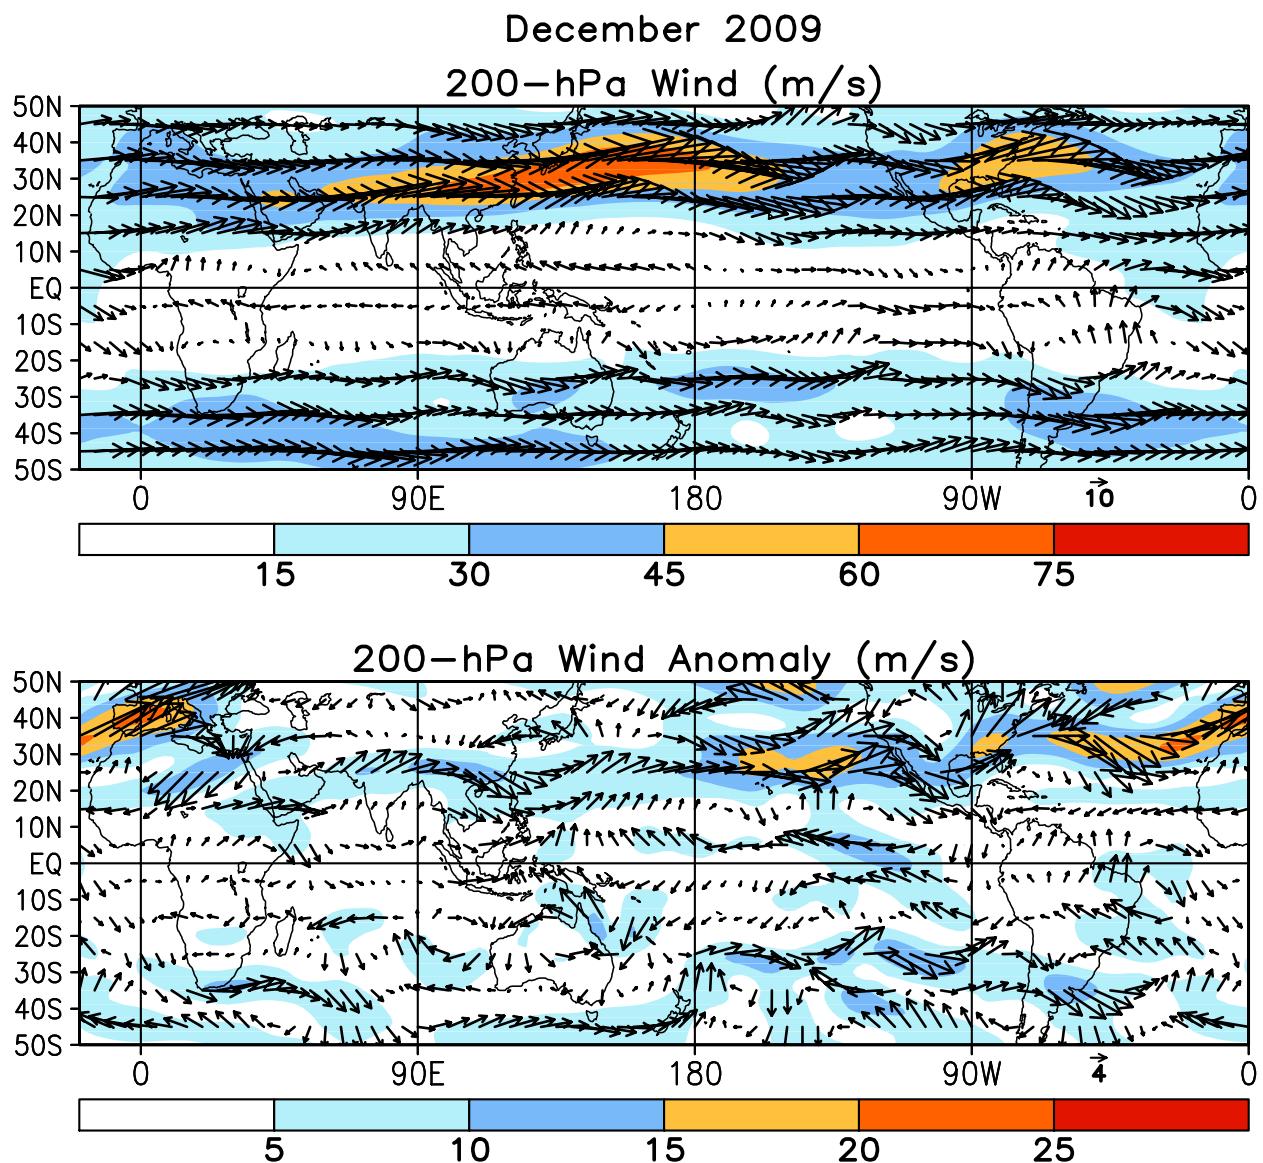

FIGURE T21. Mean (top) and anomalous (bottom) 200-hPa vector wind (CDAS/Reanalysis) for DEC 2009. Contour interval for isotachs is 15 ms^{-1} (top) and 5 ms^{-1} (bottom). Anomalies are departures from 1979–95 base period monthly means.

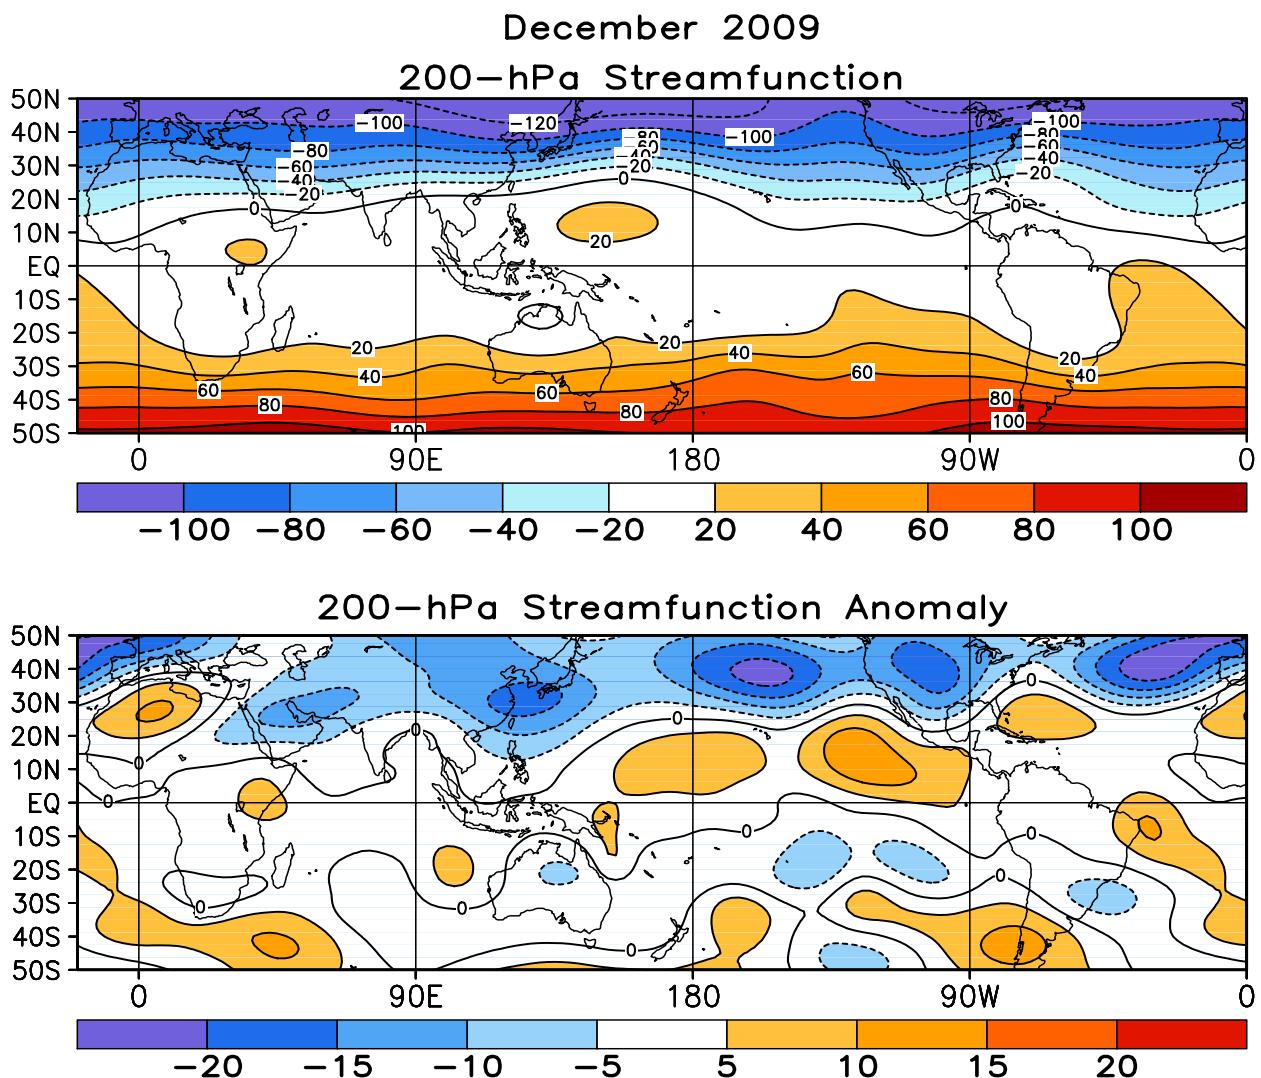

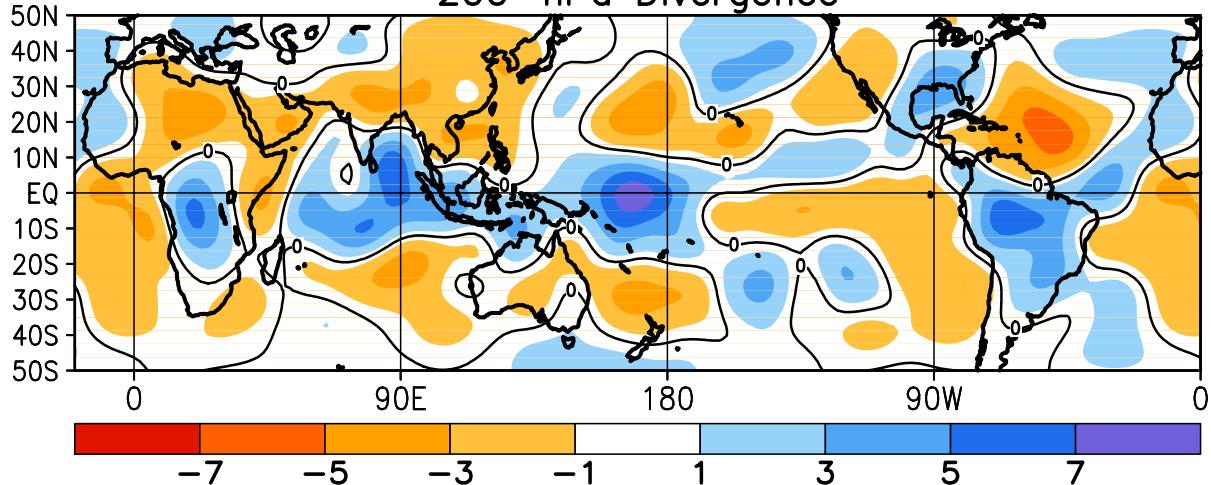

FIGURE T22. Mean (top) and anomalous (bottom) 200-hPa streamfunction (CDAS/Reanalysis). Contour interval is $20 \times 10^6 \text{ m}^2 \text{s}^{-1}$ (top) and $5 \times 10^6 \text{ m}^2 \text{s}^{-1}$ (bottom). Negative (positive) values are indicated by dashed (solid) lines. The non-divergent component of the flow is directed along the contours with speed proportional to the gradient. Thus, high (low) stream function corresponds to high (low) geopotential height in the Northern Hemisphere and to low (high) geopotential height in the Southern Hemisphere. Anomalies are departures from the 1979-1995 base period monthly means.

December 2009
200-hPa Divergence

200-hPa Divergence Anomaly

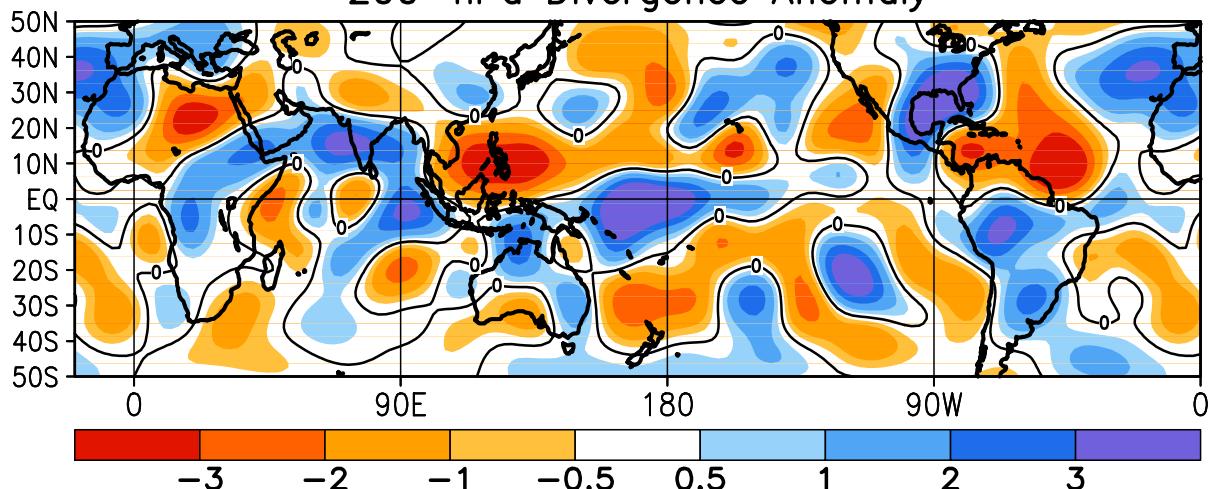

FIGURE T23. Mean (top) and anomalous (bottom) 200-hPa divergence (CDAS/Reanalysis). Divergence and anomalous divergence are shaded blue. Convergence and anomalous convergence are shaded orange. Anomalies are departures from the 1979-1995 base period monthly means.

December 2009

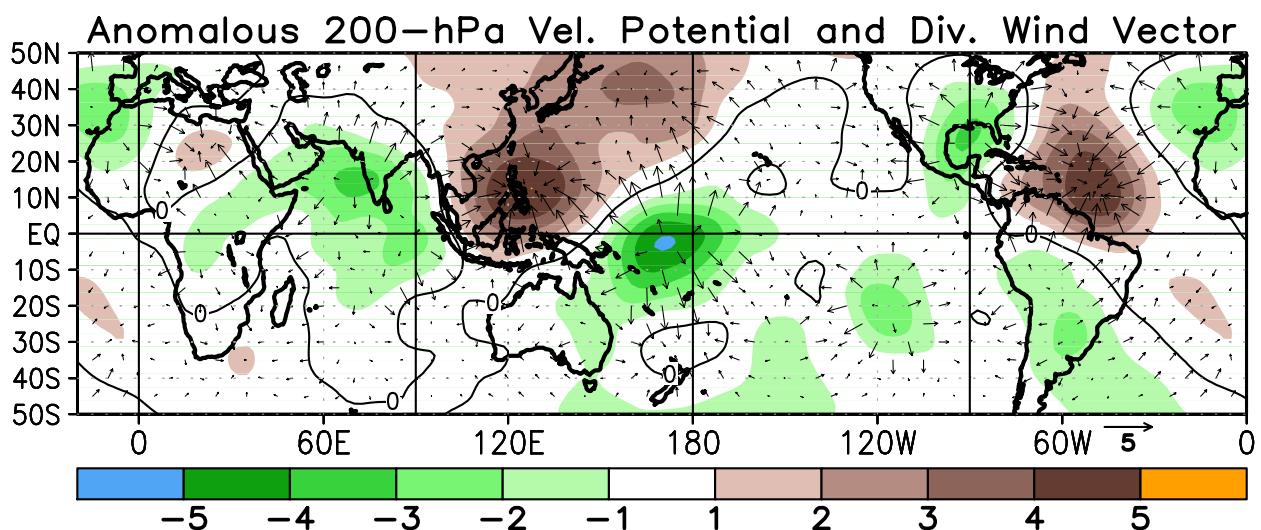

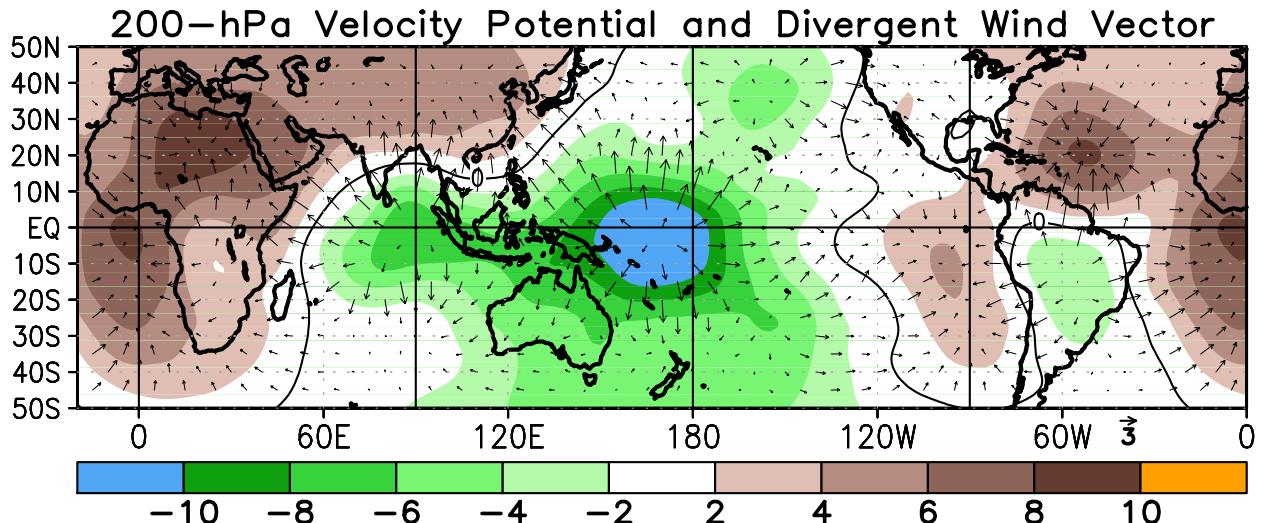

FIGURE T24. Mean (top) and anomalous (bottom) 200-hPa velocity potential ($10^6 \text{m}^2/\text{s}$) and divergent wind (CDAS/Reanalysis). Anomalies are departures from the 1979–1995 base period monthly means.

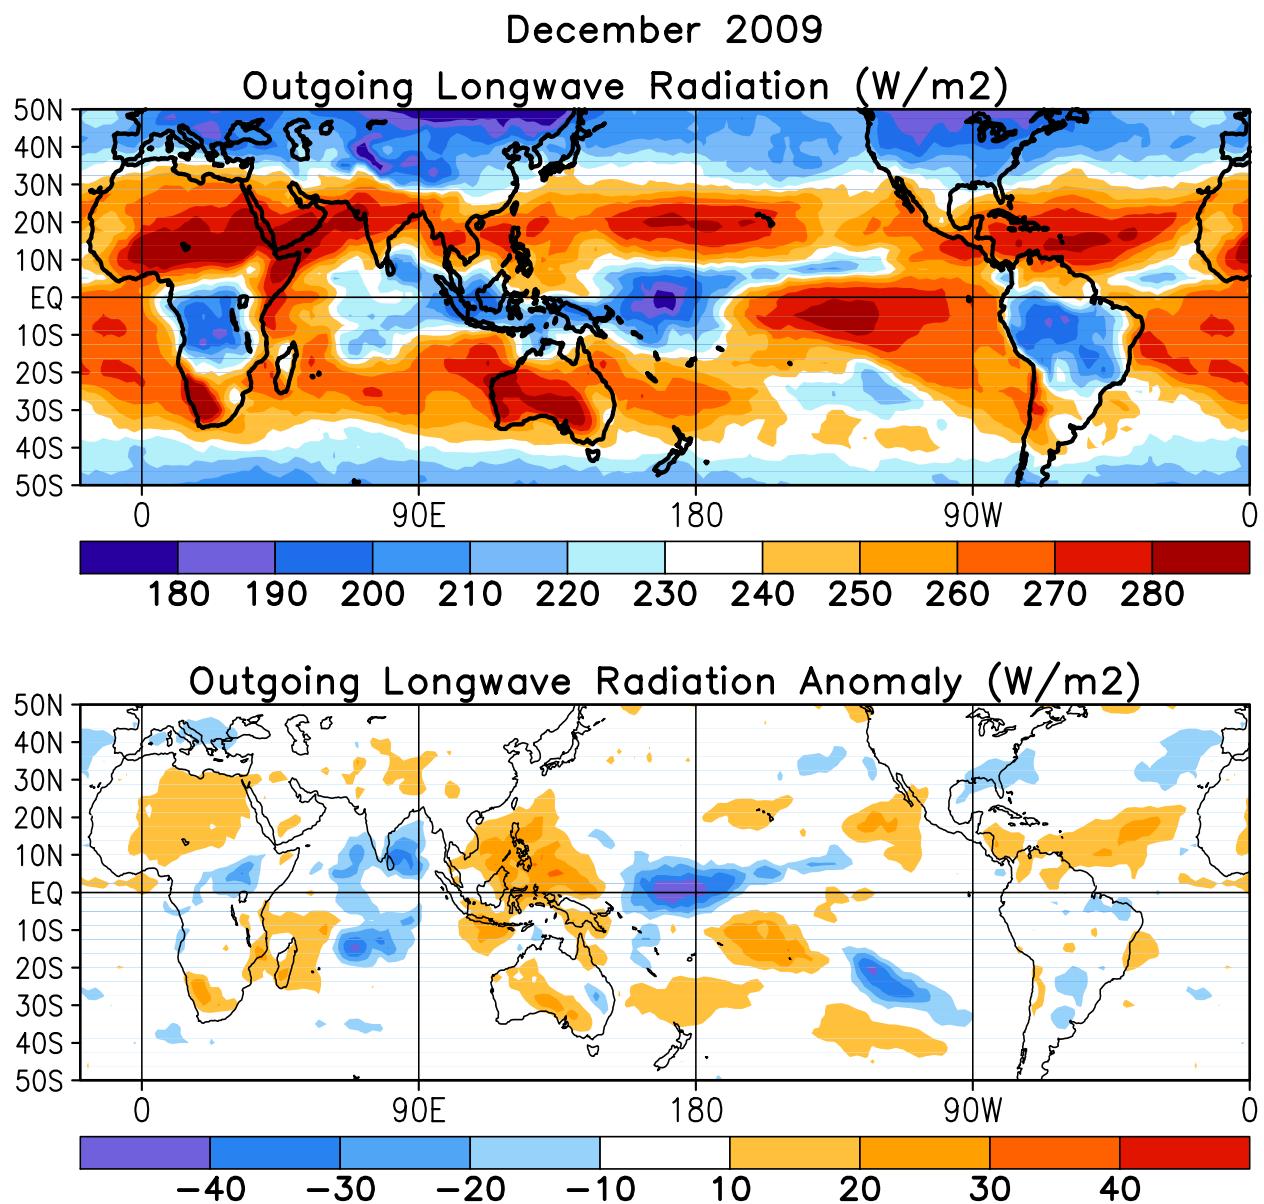

FIGURE T25. Mean (top) and anomalous (bottom) outgoing longwave radiation for DEC 2009 (NOAA 18 AVHRR IR window channel measurements by NESDIS/ORA). OLR contour interval is 20 Wm⁻² with values greater than 280 Wm⁻² indicated by dashed contours. Anomaly contour interval is 15 Wm⁻² with positive values indicated by dashed contours and light shading. Anomalies are departures from the 1979–95 base period monthly means.

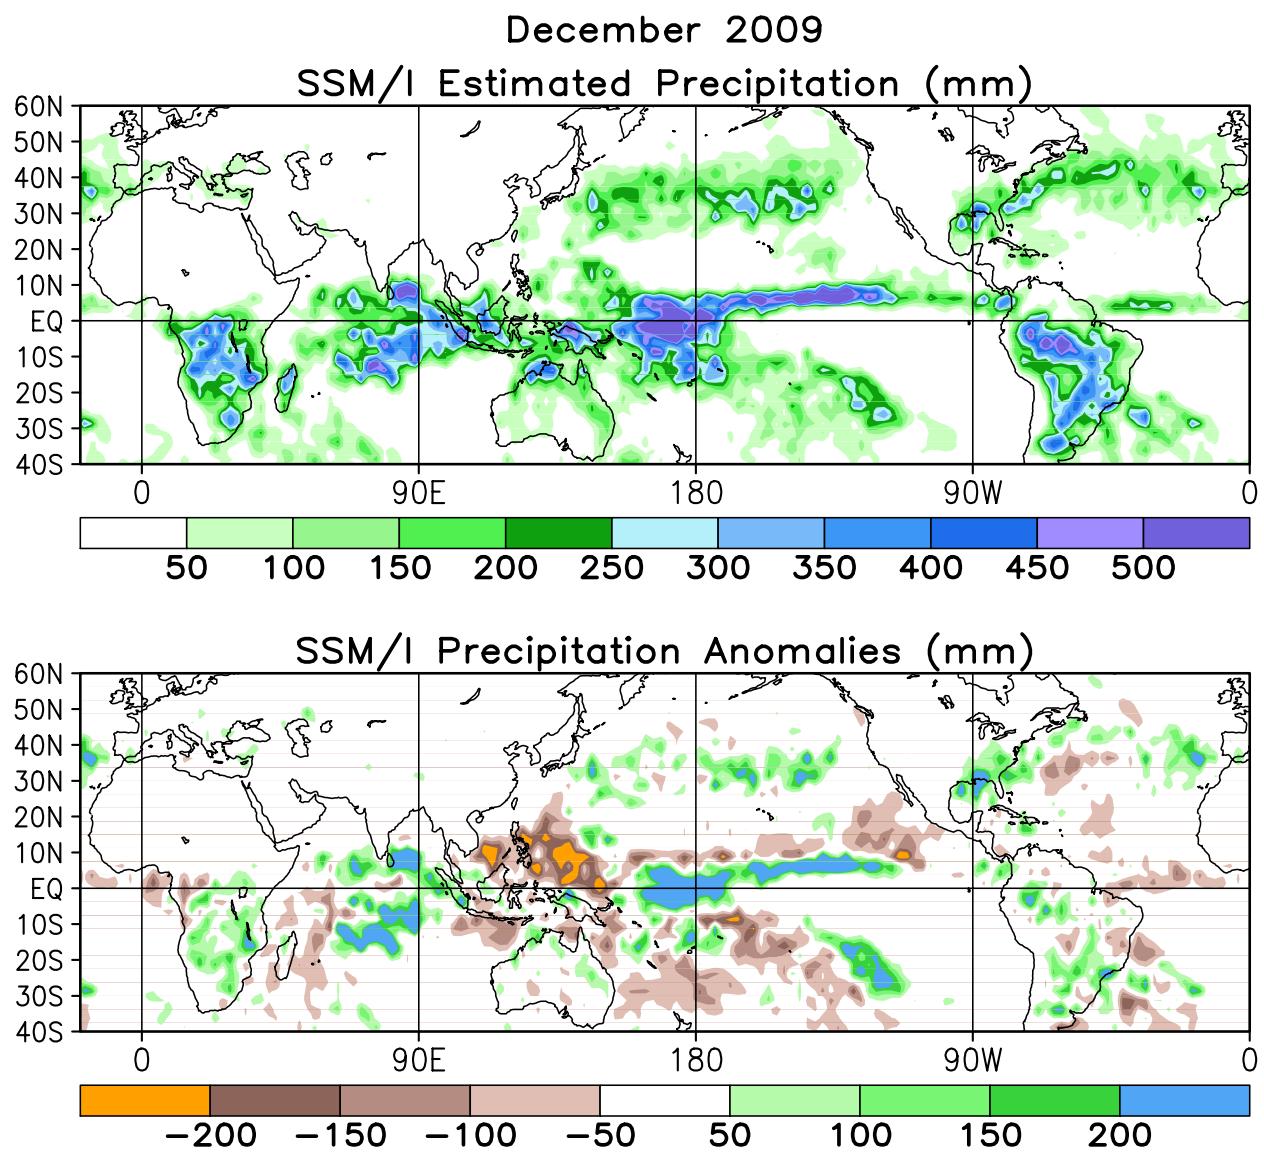

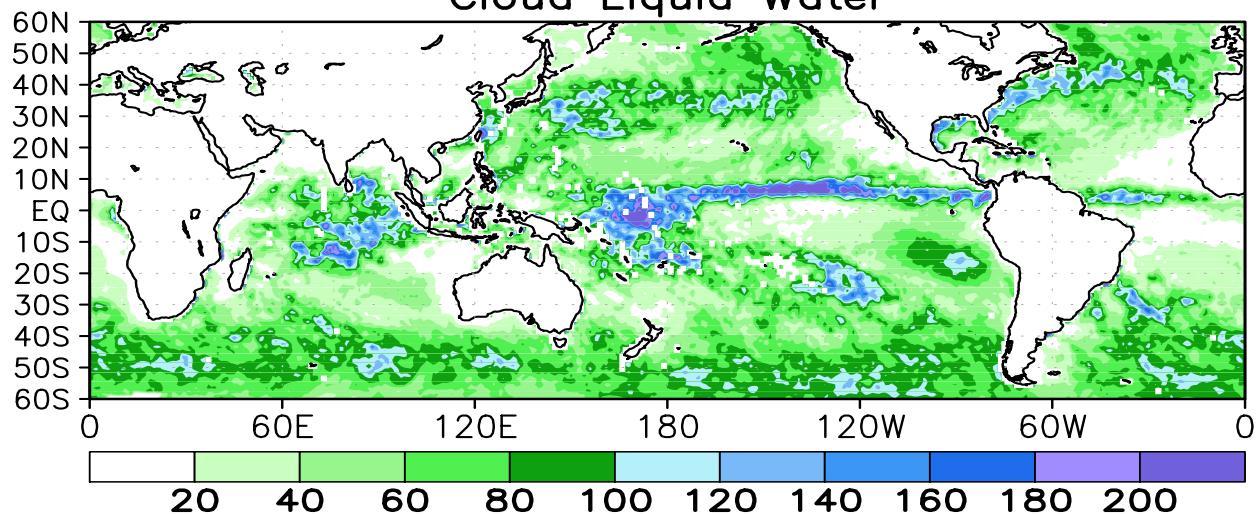

FIGURE T26. Estimated total (top) and anomalous (bottom) rainfall (mm) based on the Special Sensor Microwave/Imager (SSM/I) precipitation index (Ferraro 1997, *J. Geophys. Res.*, **102**, 16715-16735). Anomalies are computed from the 1987-2006 base period monthly means. Anomalies have been smoothed for display purposes.

December 2009
Cloud Liquid Water

Cloud Liquid Water Anomaly

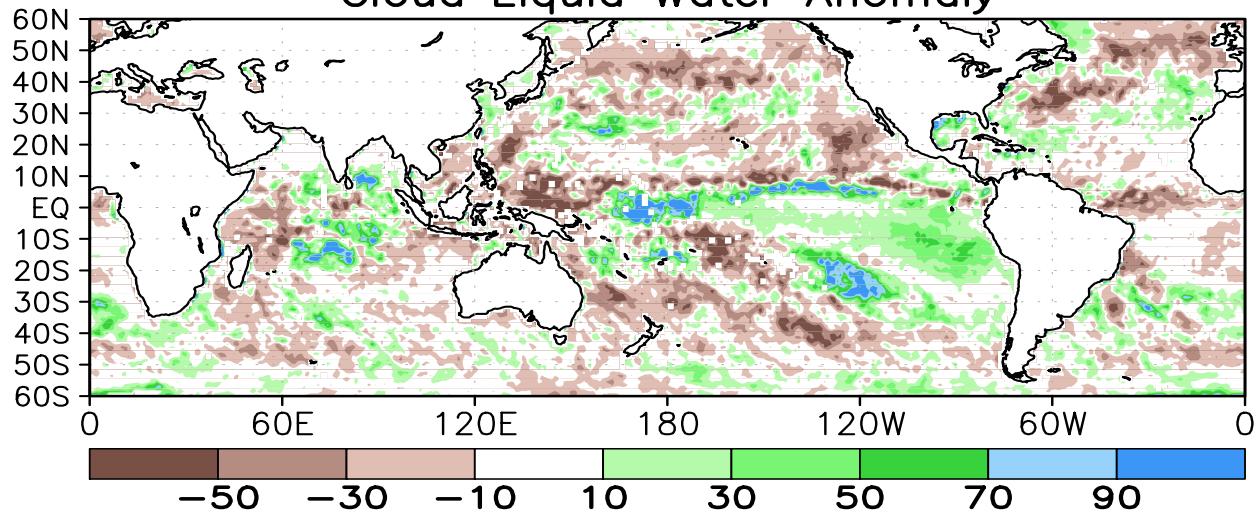

FIGURE T27. Mean (top) and anomalous (bottom) cloud liquid water (g m^{-2}) based on the Special Sensor Microwave/Imager (SSM/I) (Weng et al 1997: *J. Climate*, **10**, 1086-1098). Anomalies are calculated from the 1987-2006 base period means.

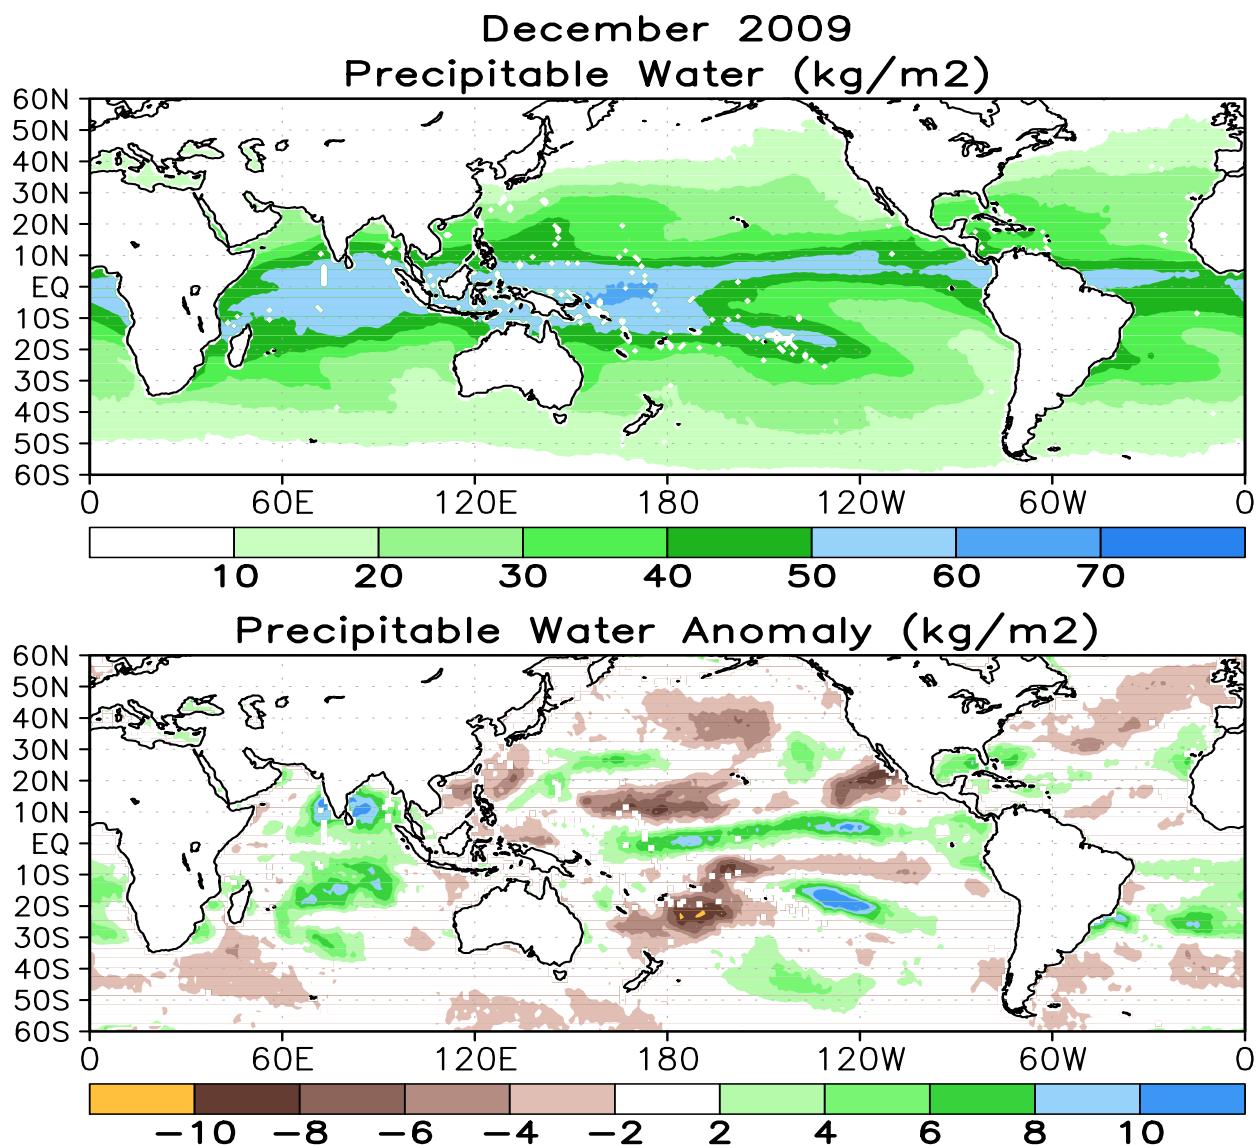

FIGURE T28. Mean (top) and anomalous (bottom) vertically integrated water vapor or precipitable water (kg m^{-2}) based on the Special Sensor Microwave/Imager (SSM/I) (Ferraro et. al, 1996: *Bull. Amer. Meteor. Soc.*, **77**, 891-905). Anomalies are calculated from the 1987-2006 base period means.

December 2009
Divergence and East–West Divergent Circulation
Mean

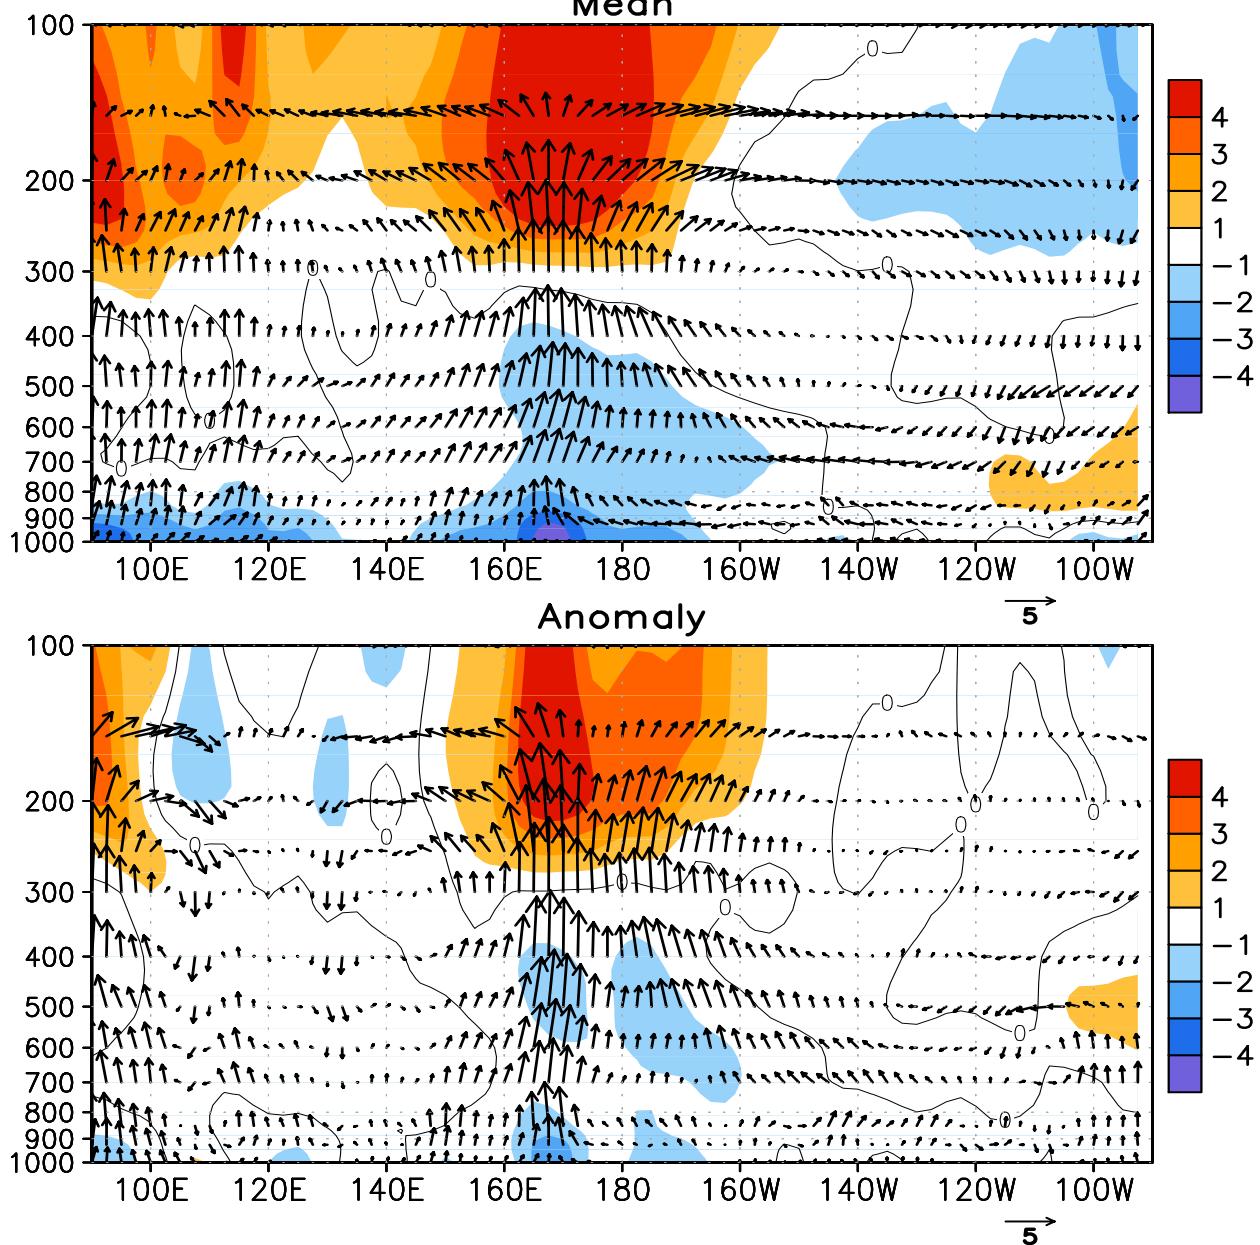

FIGURE T29. Pressure-longitude section (100E–80W) of the mean (top) and anomalous (bottom) divergence (contour interval is $1 \times 10^{-6} \text{ s}^{-1}$) and divergent circulation averaged between 5N–5S. The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the zonal wind. Red shading and solid contours denote divergence (top) and anomalous divergence (bottom). Blue shading and dashed contours denote convergence (top) and anomalous convergence (bottom). Anomalies are departures from the 1979–1995 base period monthly means.

December 2009
Divergence and West–East Divergent Circulation

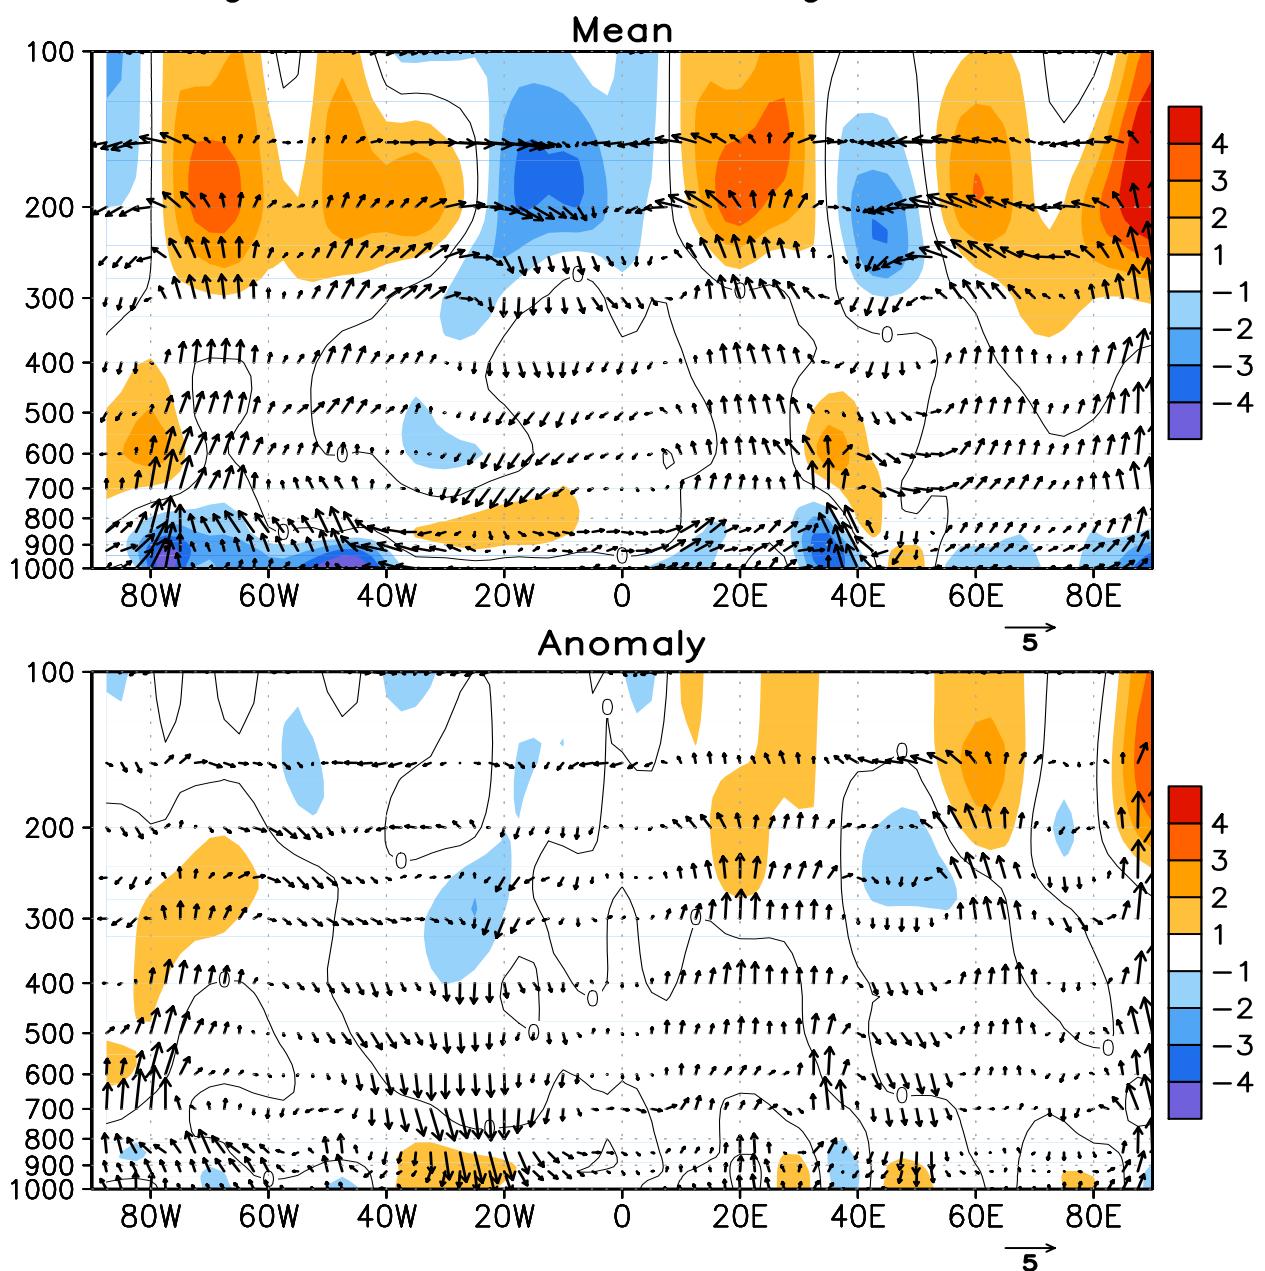

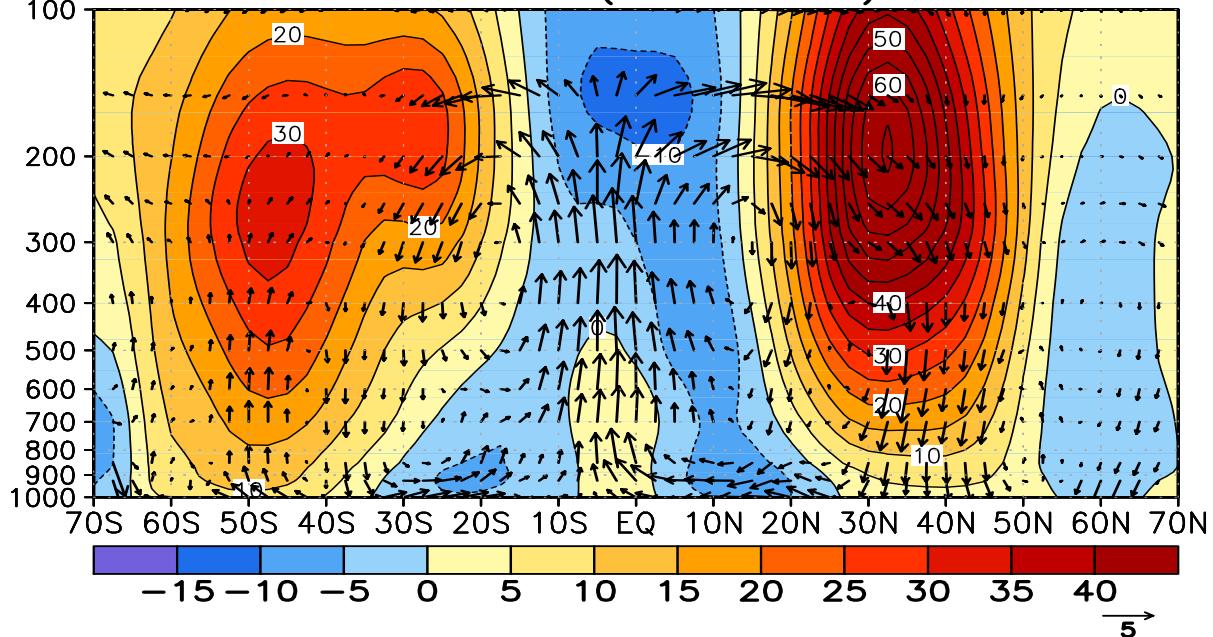

FIGURE T30. Pressure-longitude section (80W–100E) of the mean (top) and anomalous (bottom) divergence (contour interval is $1 \times 10^{-6} \text{ s}^{-1}$) and divergent circulation averaged between 5N–5S. The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the zonal wind. Red shading and solid contours denote divergence (top) and anomalous divergence (bottom). Blue shading and dashed contours denote convergence (top) and anomalous convergence (bottom). Anomalies are departures from the 1979–1995 base period monthly means.

December 2009

Zonal Wind and N–S Divergent Circulation
Western Pacific (120E–170E): Mean

Western Pacific (120E–170E): Anomaly

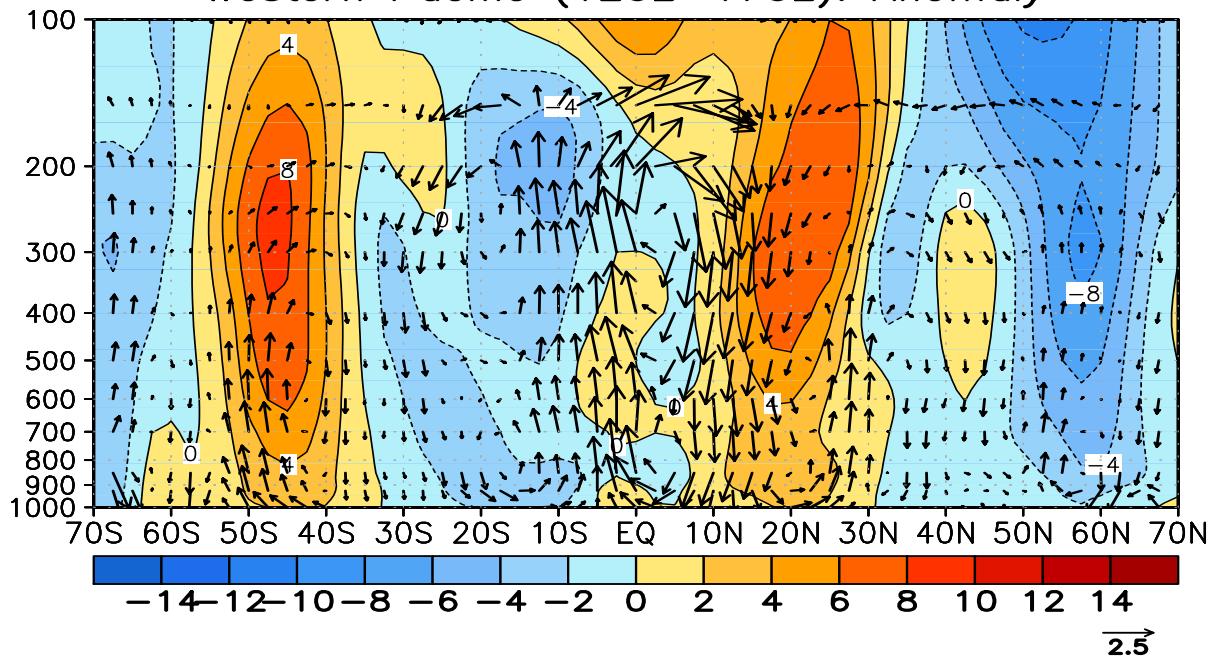

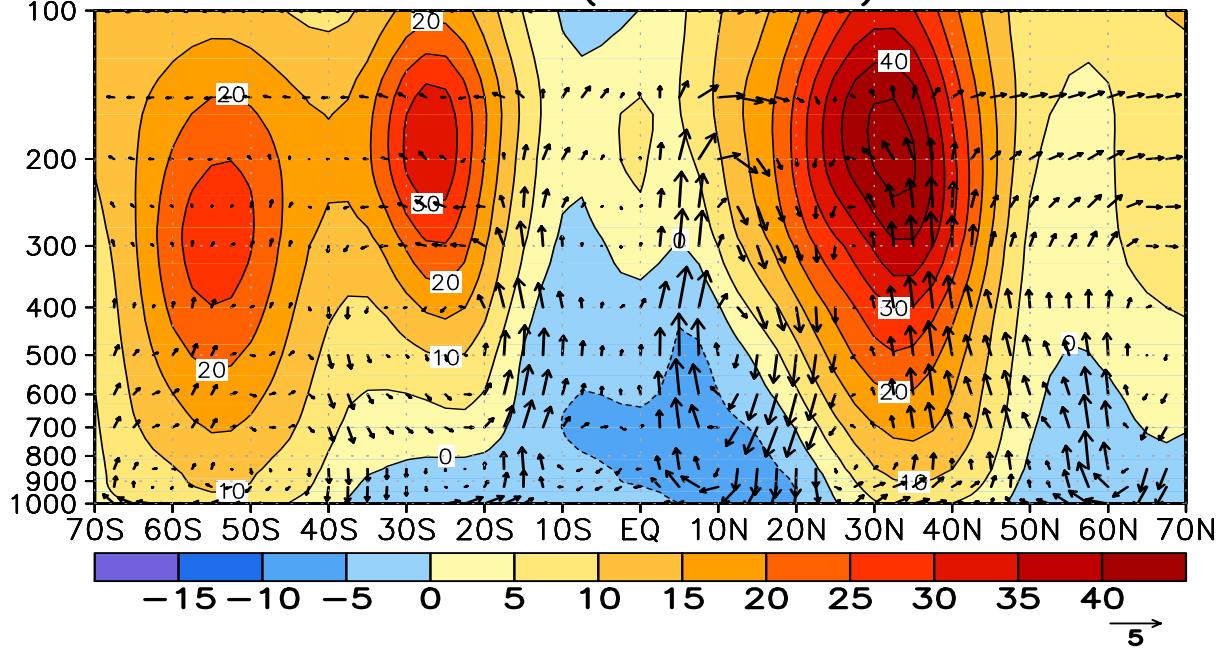

FIGURE T31. Pressure-latitude section of the mean (top) and anomalous (bottom) zonal wind (m s^{-1}) and divergent circulation averaged over the west Pacific sector (120E–170E). The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the meridional wind. Red shading and solid contours denote a westerly (top) or anomalous westerly (bottom) zonal wind. Blue shading and dashed contours denote an easterly (top) or anomalous easterly (bottom) zonal wind. Anomalies are departures from the 1979–1995 base period monthly means.

December 2009

Zonal Wind and N–S Divergent Circulation
Eastern Pacific (130W–180W): Mean

Eastern Pacific (130W–180W): Anomaly

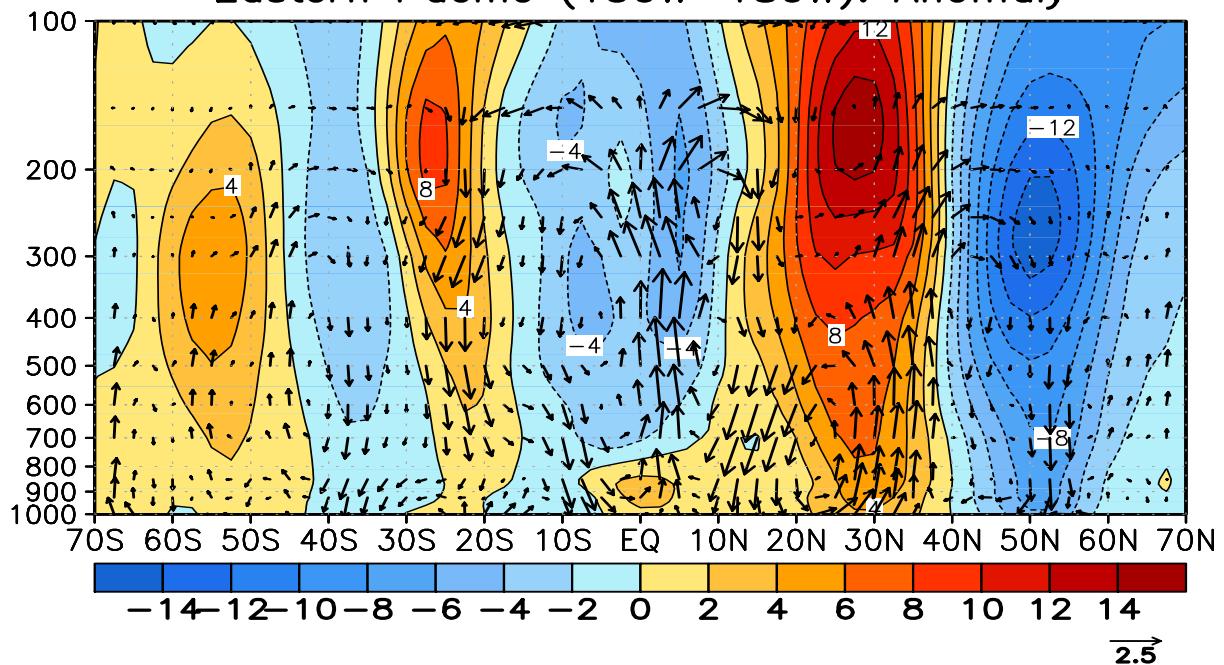

FIGURE T32. Pressure-latitude section of the mean (top) and anomalous (bottom) zonal wind (m s^{-1}) and divergent circulation averaged over the central Pacific sector (130W–180W). The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the meridional wind. Red shading and solid contours denote a westerly (top) or anomalous westerly (bottom) zonal wind. Blue shading and dashed contours denote an easterly (top) or anomalous easterly (bottom) zonal wind. Anomalies are departures from the 1979–1995 base period monthly means.

Tropical Pacific Drifting Buoys

R. Lumpkin/M. Pazos, AOML, Miami

During December 2009, 407 satellite-tracked surface drifting buoys, 76% with subsurface drogues attached for measuring mixed layer currents, were reporting from the tropical Pacific. Dramatic eastward anomalies of 50-70 cm/s were measured by many equatorial drifters in the central part of the basin, with anomalies as high as 80cm/s in the longitude band 160W to the dateline. This El Niño pattern was associated with hot equatorial SST anomalies of +1.5 to +3.0C from 130W to 180. Outside of the equatorial band, and west of about 110W, most drifters measured warm (+0.5 to +1.5C) SST anomalies. Slightly cold SST anomalies (-0.5 to -1.5C) were observed in the southeasternmost corner of the domain as in the previous month.

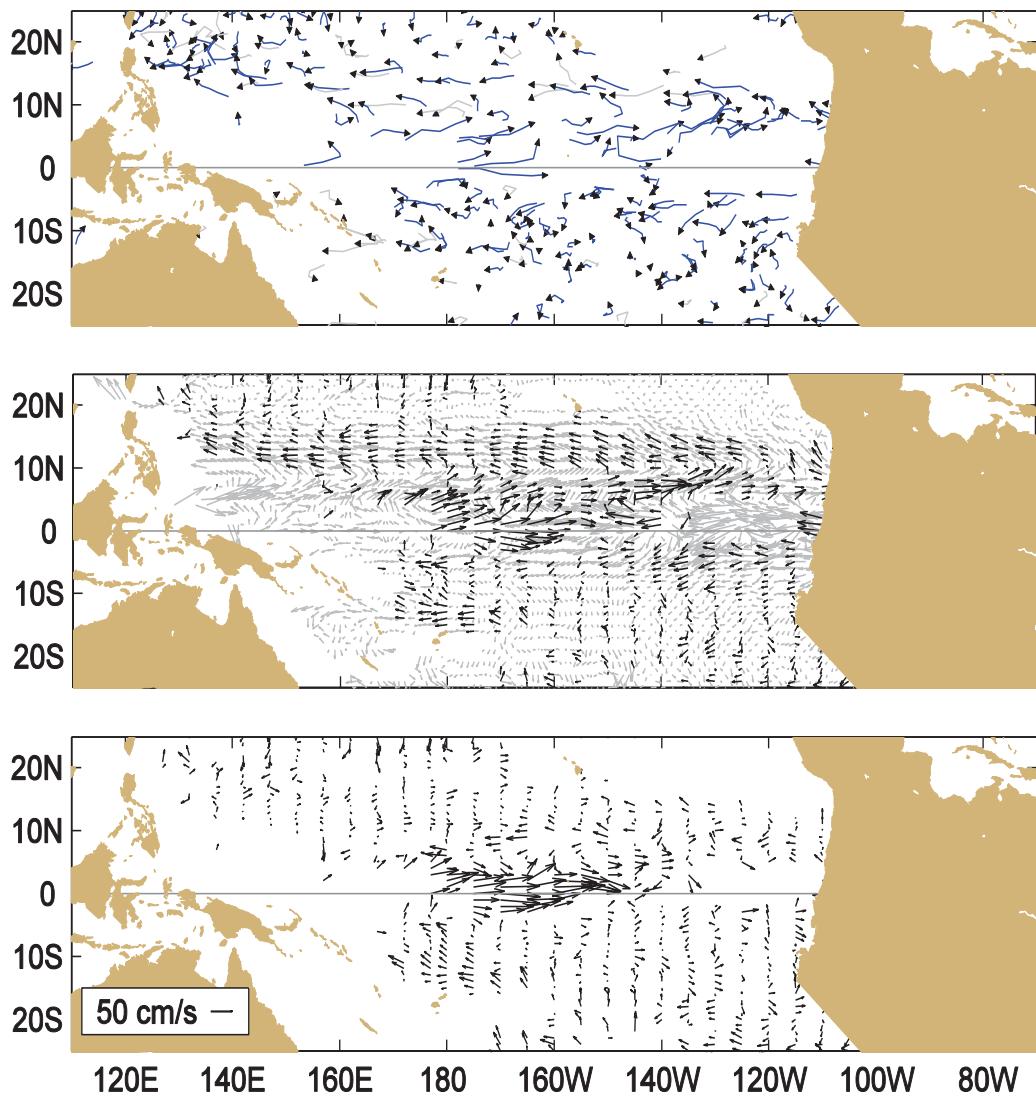

Figure A1.1 Top: Movements of drifting buoys in the tropical Pacific Ocean during December 2009. The linear segments of each trajectory represent a one week displacement. Trajectories of buoys which have lost their subsurface drogues are gray; those with drogues are black.

Middle: Monthly mean currents calculated from all buoys 1993-2002 (gray), and currents measured by the drogued buoys this month (black) smoothed by an optimal filter.

Bottom: Anomalies from the climatological monthly mean currents for this month.

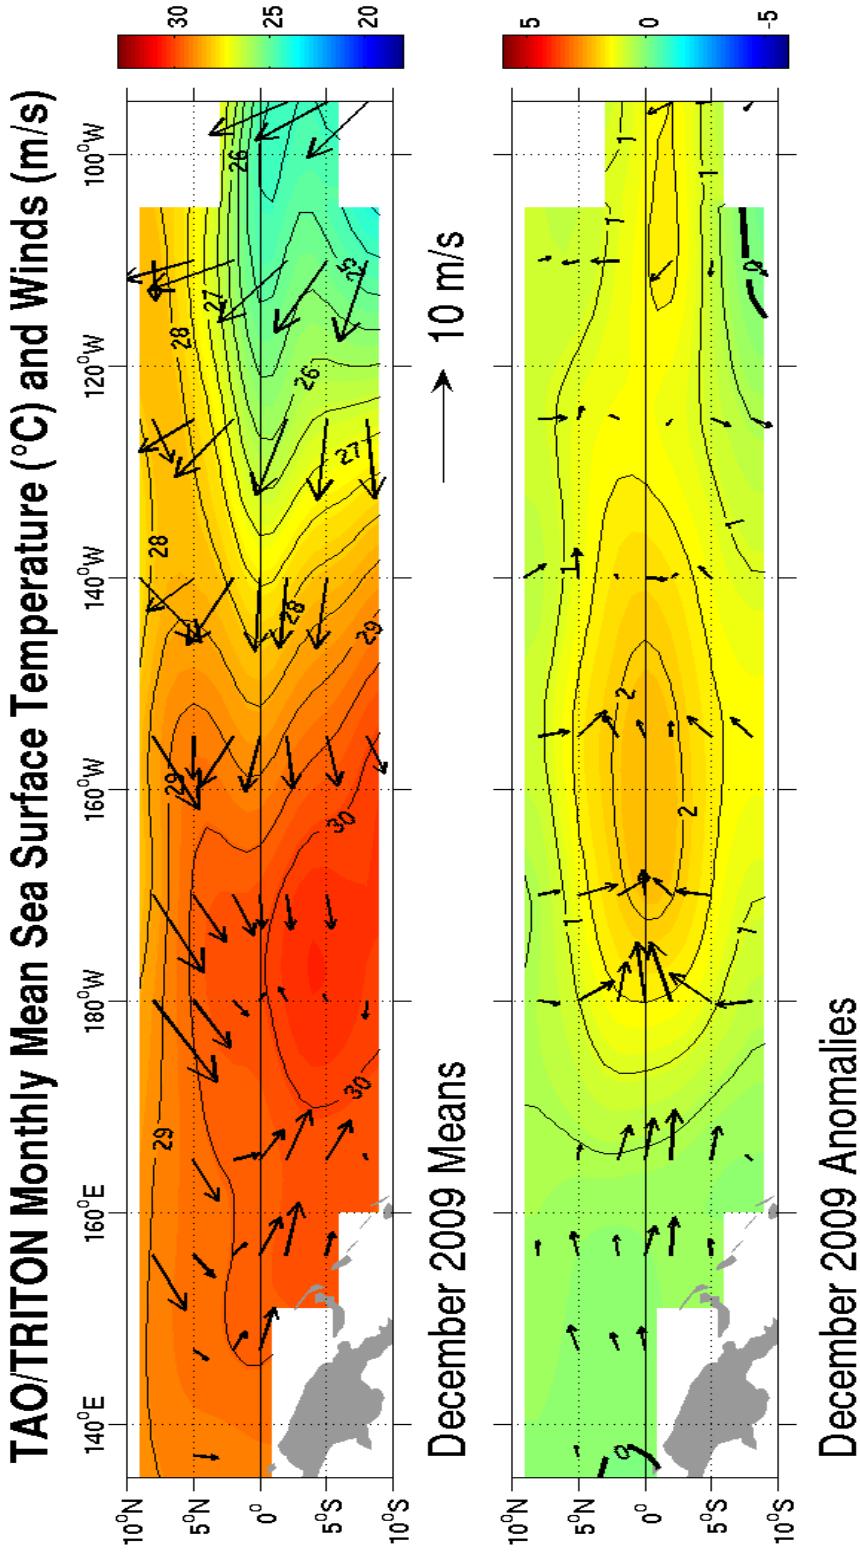

FIGURE A1.2. Wind Vectors and sea surface temperature (SSTs) from the TAO/TRITON mooring array. Top panel shows monthly means; bottom panel shows monthly anomalies from the COADS wind climatology and Reynolds SST climatology (1971-2000). The TAO/TRITON array is presently supported by the United States (NOAA), Japan (STA), and France (IRD). Further information is available from Richard L. Crout (NOAA/NDBC).

Five Day Zonal Wind, SST, and 20°C Isotherm Depth 2°S to 2°N Average

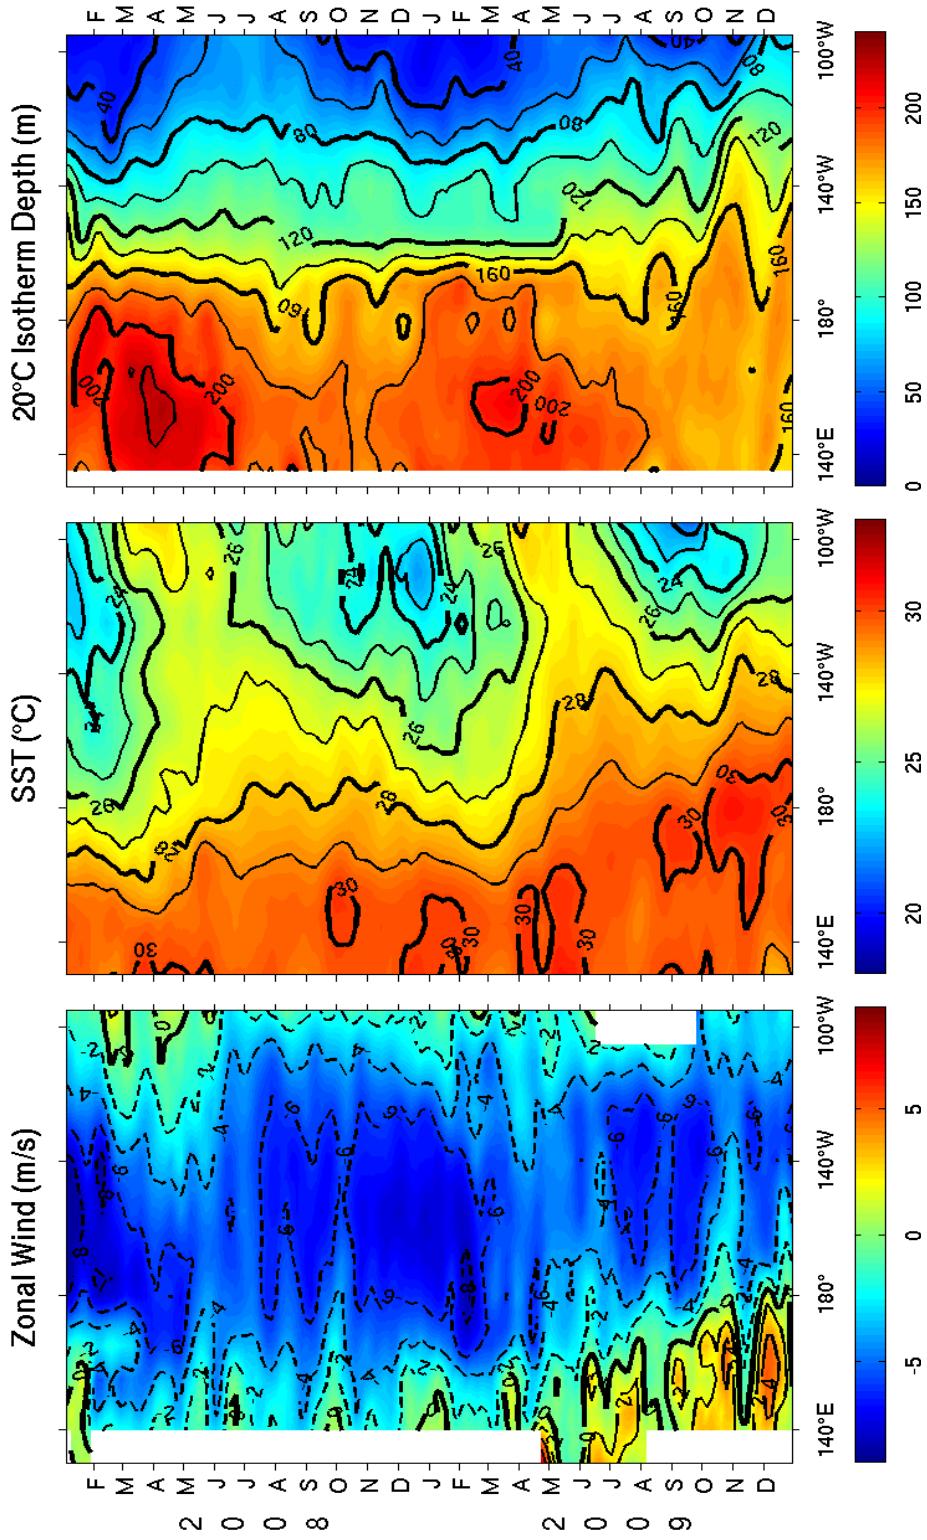

FIGURE A1.3. Time-longitude sections of surface zonal winds (m s^{-1}), sea surface temperature (°C) and 20°C isotherm depth (m) for the past 24 months. Analysis is based on 5-day averages of moored time series data from the TAO/TRITON array. Positive winds are westerly. Squares on the abscissas indicate longitude where data were available at the start of the time series (top) and end of the time series (bottom). The TAO/TRITON array is presently supported by the United States (NOAA), Japan (STA), and France (IRD). Further information is available from Richard L. Crout (NOAA/NDBC).

Five Day Zonal Wind, SST, and 20°C Isotherm Depth Anomalies 2°S to 2°N Average

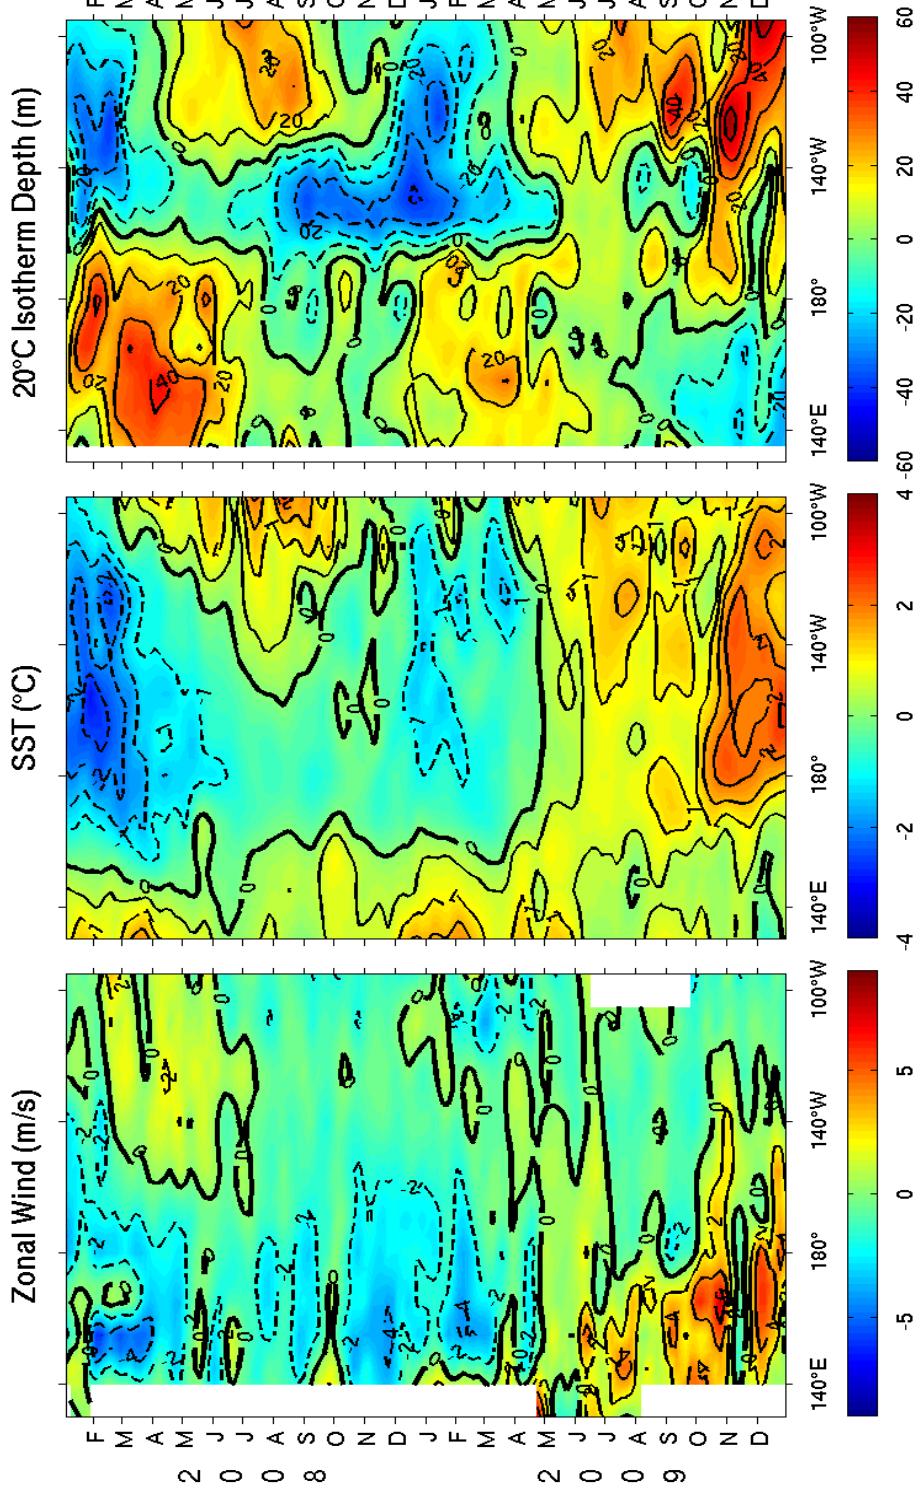

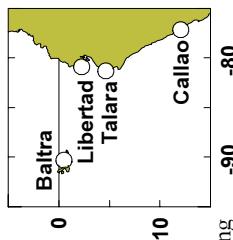

FIGURE A1.4. Time-longitude sections of surface zonal winds (m s^{-1}), sea surface temperature (C) and 20C isotherm depth (m) for the past 24 months. Analysis is based on 5-day averages of moored time series data from the TAO/TRITON array. Anomalies are relative to monthly climatologis cubic spline fitted to 5-day intervals (COADS winds, Reynolds SST, CTD/XBT 20C depth). Positive winds are westerly. Squares on the abscissas indicate longitude where data were available at the start of the time series (top) and end of the time series (bottom). The TAO/TRITON array is presently supported by the United States (NOAA), Japan (STA), and France (IRD). Further information is available from Richard L. Crout (NOAA)

Sea Surface Temperature and Sea Level From Eastern Pacific GOES Stations

David B. Enfield, NOAA/AOML, 4301 Rickenbacker Cswy, Miami FL 33149, USA

Instituto Oceanográfico de la Armada, Guayaquil, ECUADOR

Dirección de Hidrografía y Navegación de la Marina, Callao, PERU

In cooperation with institutions in Peru and Ecuador, NOAA-AOML maintained a network of coastal stations reporting SST and sea level in real time (via satellite downlink) during the TOGA program, from 1985 to 1995. The South American partners took over full operational responsibility thereafter while NOAA-AOML assumed a data management role, continuing publication of these monthly reports along with their partners. The five-day averages (pentads) at critical stations give us an effective means of monitoring coastal conditions with good time resolution and compact data volume.

Late November saw a rise in sea level at Callao and two weeks later came a 2+°C anomalous warming at Talara, and in the last week of December the warming reached Callao. We have learned, however, that even with almost 2 months of 2+°C conditions offshore, Guayaquil has still seen no rain, unusual for the warm season.

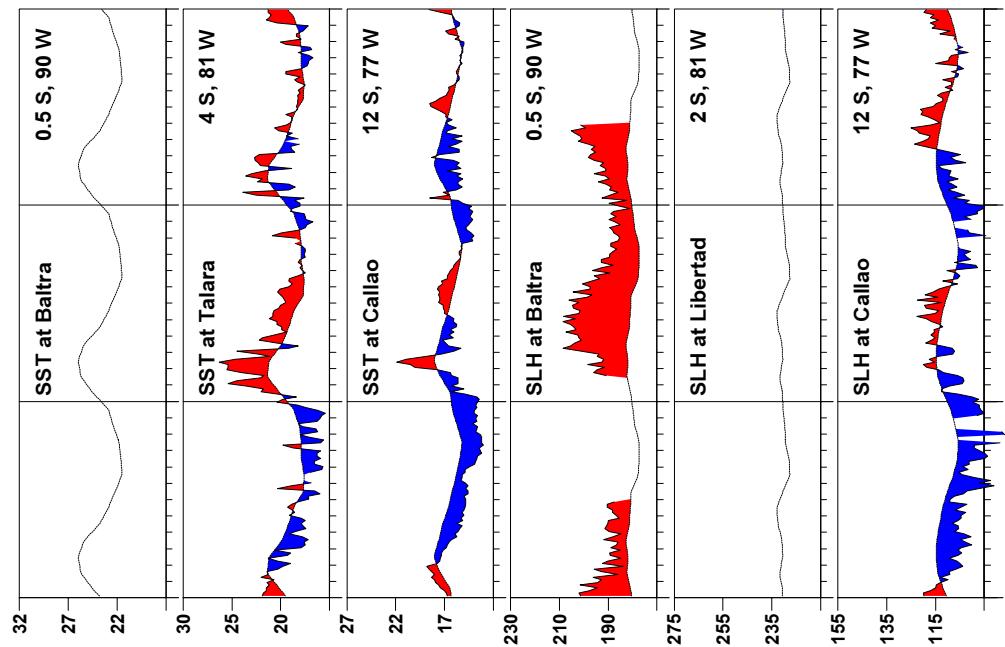

FIGURE A1.5. Five-day averages of sea surface temperature (SST, °C) and sea level height (SLH, cm) from GOES receiving stations in Ecuador & Peru. Dashed line and shading show climatology, departures.

Forecast Forum

The canonical correlation analysis (CCA) forecast of SST in the central Pacific (Barnett et al. 1988, *Science*, **241**, 192196; Barnston and Ropelewski 1992, *J. Climate*, **5**, 13161345), is shown in **Figs. F1 and F2**. This forecast is produced routinely by the Prediction Branch of the Climate Prediction Center. The predictions from the National Centers for Environmental Prediction (NCEP) Coupled Forecast System Model (CFS03) are presented in **Figs. F3 and F4a, F4b**. Predictions from the Markov model (Xue, et al. 2000: *J. Climate*, **13**, 849871) are shown in **Figs. F5 and F6**. Predictions from the latest version of the LDEO model (Chen et al. 2000: *Geophys. Res. Lett.*, **27**, 25852587) are shown in **Figs. F7 and F8**. Predictions using linear inverse modeling (Penland and Magorian 1993: *J. Climate*, **6**, 10671076) are shown in **Figs. F9 and F10**. Predictions from the Scripps / Max Planck Institute (MPI) hybrid coupled model (Barnett et al. 1993: *J. Climate*, **6**, 15451566) are shown in **Fig. F11**. Predictions from the ENSOCLIPER statistical model (Knaff and Landsea 1997, *Wea. Forecasting*, **12**, 633652) are shown in **Fig. F12**. Niño 3.4 predictions are summarized in **Fig. F13**, provided by the Forecasting and Prediction Research Group of the IRI.

The CPC and the contributors to the **Forecast Forum** caution potential users of this predictive information that they can expect only modest skill.

ENSO Alert System Status

El Niño Advisory

Outlook

El Niño is expected to continue at least into the Northern Hemisphere spring 2010.

Discussion

El Niño strengthened during December 2009, with above-average sea surface temperatures (SST) encompassing the central and eastern equatorial Pacific Ocean (**Fig. T18**). The Niño-3.4 index increased slightly with the most recent monthly value reaching +1.8°C (**Table T2**). Consistent with this warmth, equatorial upper-ocean heat content anomalies remained positive. Subsurface temperature anomalies exceeded +2°C across much of the equatorial Pacific (**Fig. T17**), with the largest departures seen in the eastern part of the basin at the end of the month. Equatorial low-level westerly and upper-level easterly wind anomalies were also consistent with El Niño (**Figs. T20, T21**), along with a continuation of suppressed convection over Indonesia and enhanced convection over the western and central equatorial Pacific (**Fig. T25**). Collectively, these oceanic and atmospheric anomalies reflect a strong El Niño.

The models continue to disagree on the eventual peak strength of El Niño (**Figs. F1-F13**). At this time, it is expected that the 3-month Niño-3.4 SST average will exceed +1.5°C during the winter (e.g. November-December-January and December-January-February). Regardless of its precise peak strength, El Niño is expected to exert a significant influence on the global weather and climate in the coming months. Most models indicate that SST anomalies in the Niño-3.4 region will begin to decrease in early 2010, and that El Niño will persist through April-May-June 2010.

Weekly updates of oceanic and atmospheric conditions are available on the Climate Prediction Center homepage ([El Niño/La Niña Current Conditions and Expert Discussions](#)).

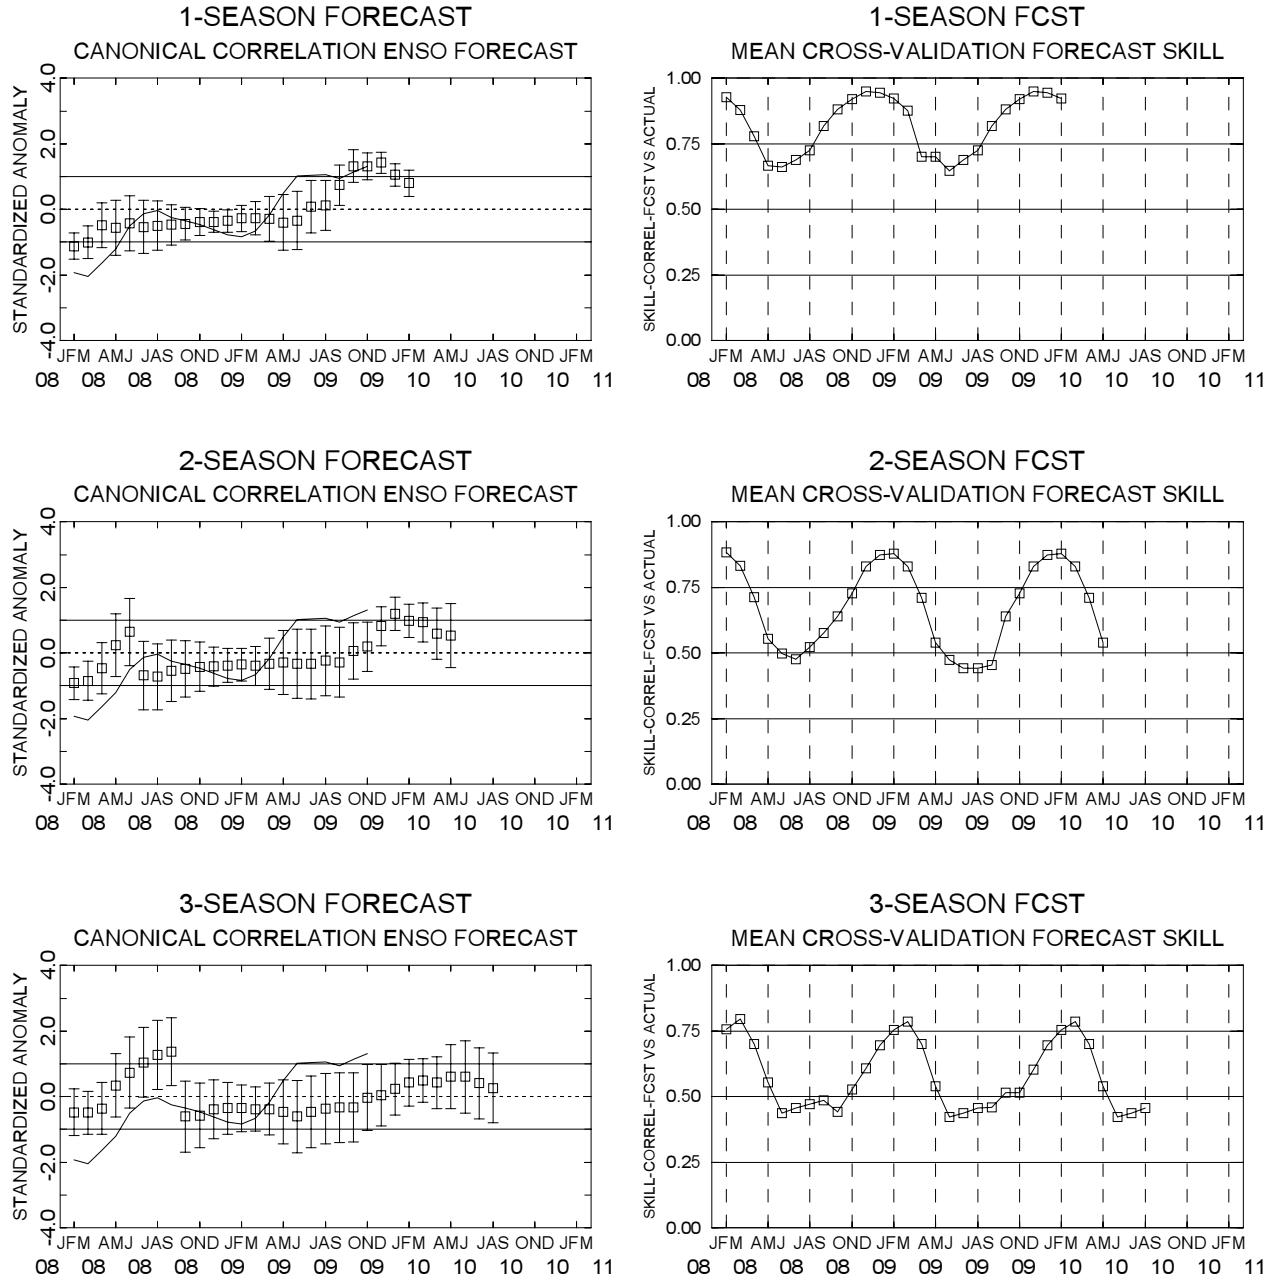

FIGURE F1. Canonical correlation analysis (CCA) sea surface temperature (SST) anomaly prediction for the central Pacific (5°N to 5°S , 120°W to 170°W) (Barnston and Ropelewski, 1992, *J. Climate*, **5**, 1316-1345). The three plots on the left hand side are, from top to bottom, the 1-season, 2-season, and 3-season lead forecasts. The solid line in each forecast represents the observed SST standardized anomaly through the latest month. The small squares at the mid-points of the forecast bars represent the real-time CCA predictions based on the anomalies of quasi-global sea level pressure and on the anomalies of tropical Pacific SST, depth of the 20°C isotherm and sea level height over the prior four seasons. The vertical lines represent the one standard deviation error bars for the predictions based on past performance. The three plots on the right side are skills, corresponding to the predicted and observed SST. The skills are derived from cross-correlation tests from 1956 to present. These skills show a clear annual cycle and are inversely proportional to the length of the error bars depicted in the forecast time series.

0-4 SEASON LEAD FORECAST CANONICAL CORRELATION ENSO FORECAST

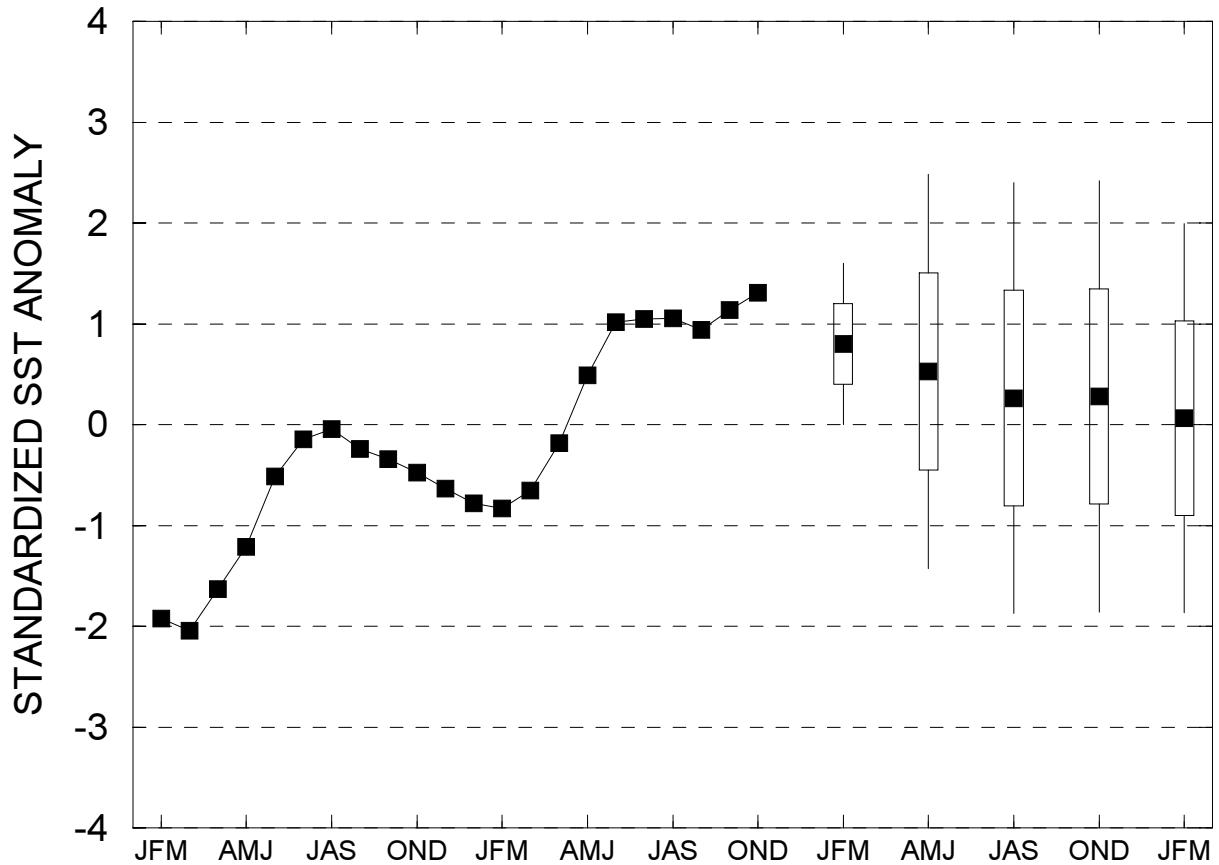

FIGURE F2. Canonical Correlation Analysis (CCA) forecasts of sea-surface temperature anomalies for the Nino 3.4 region (5N-5S, 120W-170W) for the upcoming five consecutive 3-month periods. Forecasts are expressed as standardized SST anomalies. The CCA predictions are based on anomaly patterns of SST, depth of the 20C isotherm, sea level height, and sea level pressure. Small squares at the midpoints of the vertical forecast bars represent the CCA predictions, and the bars show the one (thick) and two (thin) standard deviation errors. The solid continuous line represents the observed standardized three-month mean SST anomaly in the Nino 3.4 region up to the most recently available data.

Last update: Thu Dec 3 2009

Initial conditions: 22Nov2009–01Dec2009

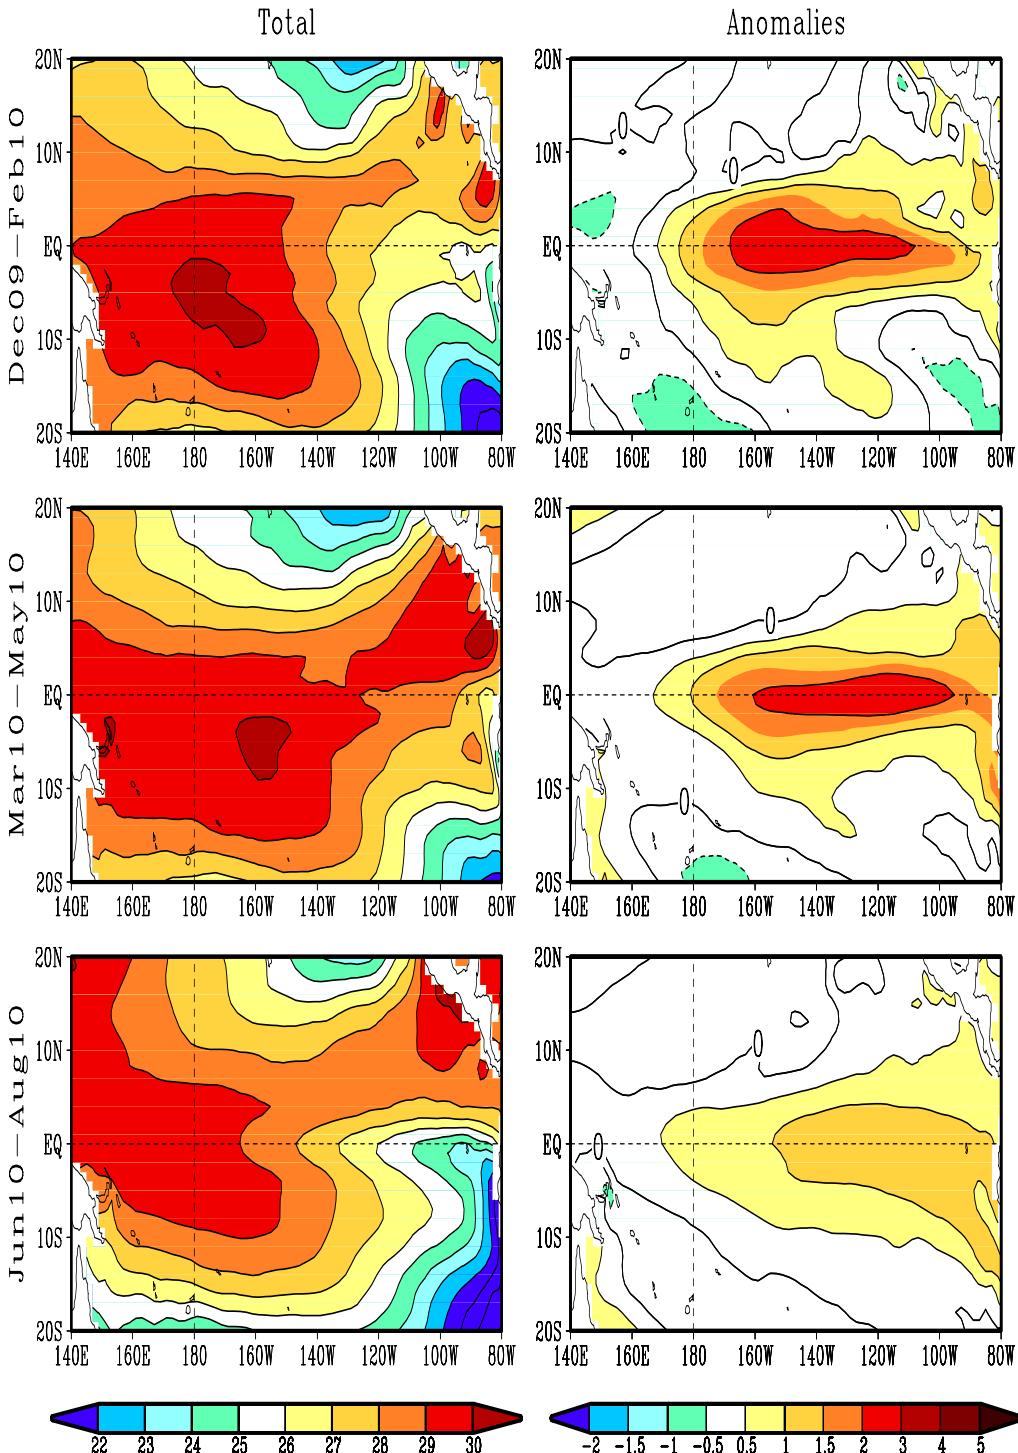

FIGURE F3. Predicted 3-month average sea surface temperature (left) and anomalies (right) from the NCEP Coupled Forecast System Model (CFS03). The forecasts consist of 40 forecast members. Contour interval is 1°C , with additional contours for 0.5°C and -0.5°C . Negative anomalies are indicated by dashed contours.

Last update: Thu Dec 3 2009
Initial conditions: 22Nov2009–01Dec2009

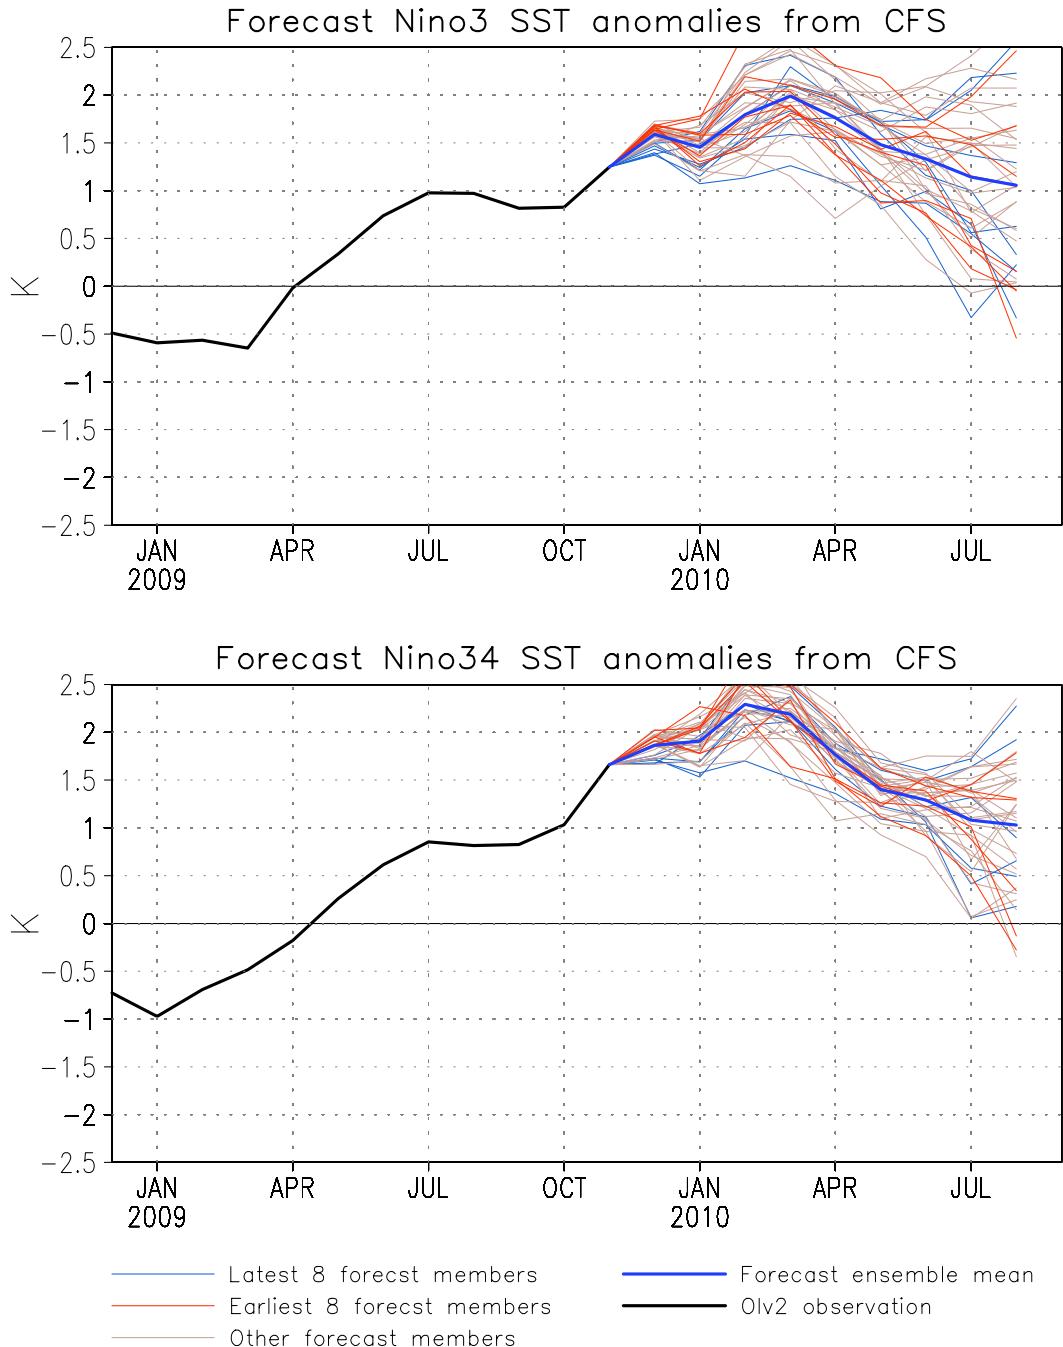

FIGURE F4. Predicted and observed sea surface temperature (SST) anomalies for the Nino 3 (top) and Nino 3.4 (bottom) regions from the NCEP Coupled Forecast System Model (CFS03). The forecasts consist of 40 forecast members. The ensemble mean of all 40 forecast members is shown by the blue line, individual members are shown by thin lines, and the observation is indicated by the black line. The Nino-3 region spans the eastern equatorial Pacific between 5N-5S, 150W-90W. The Nno 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W.

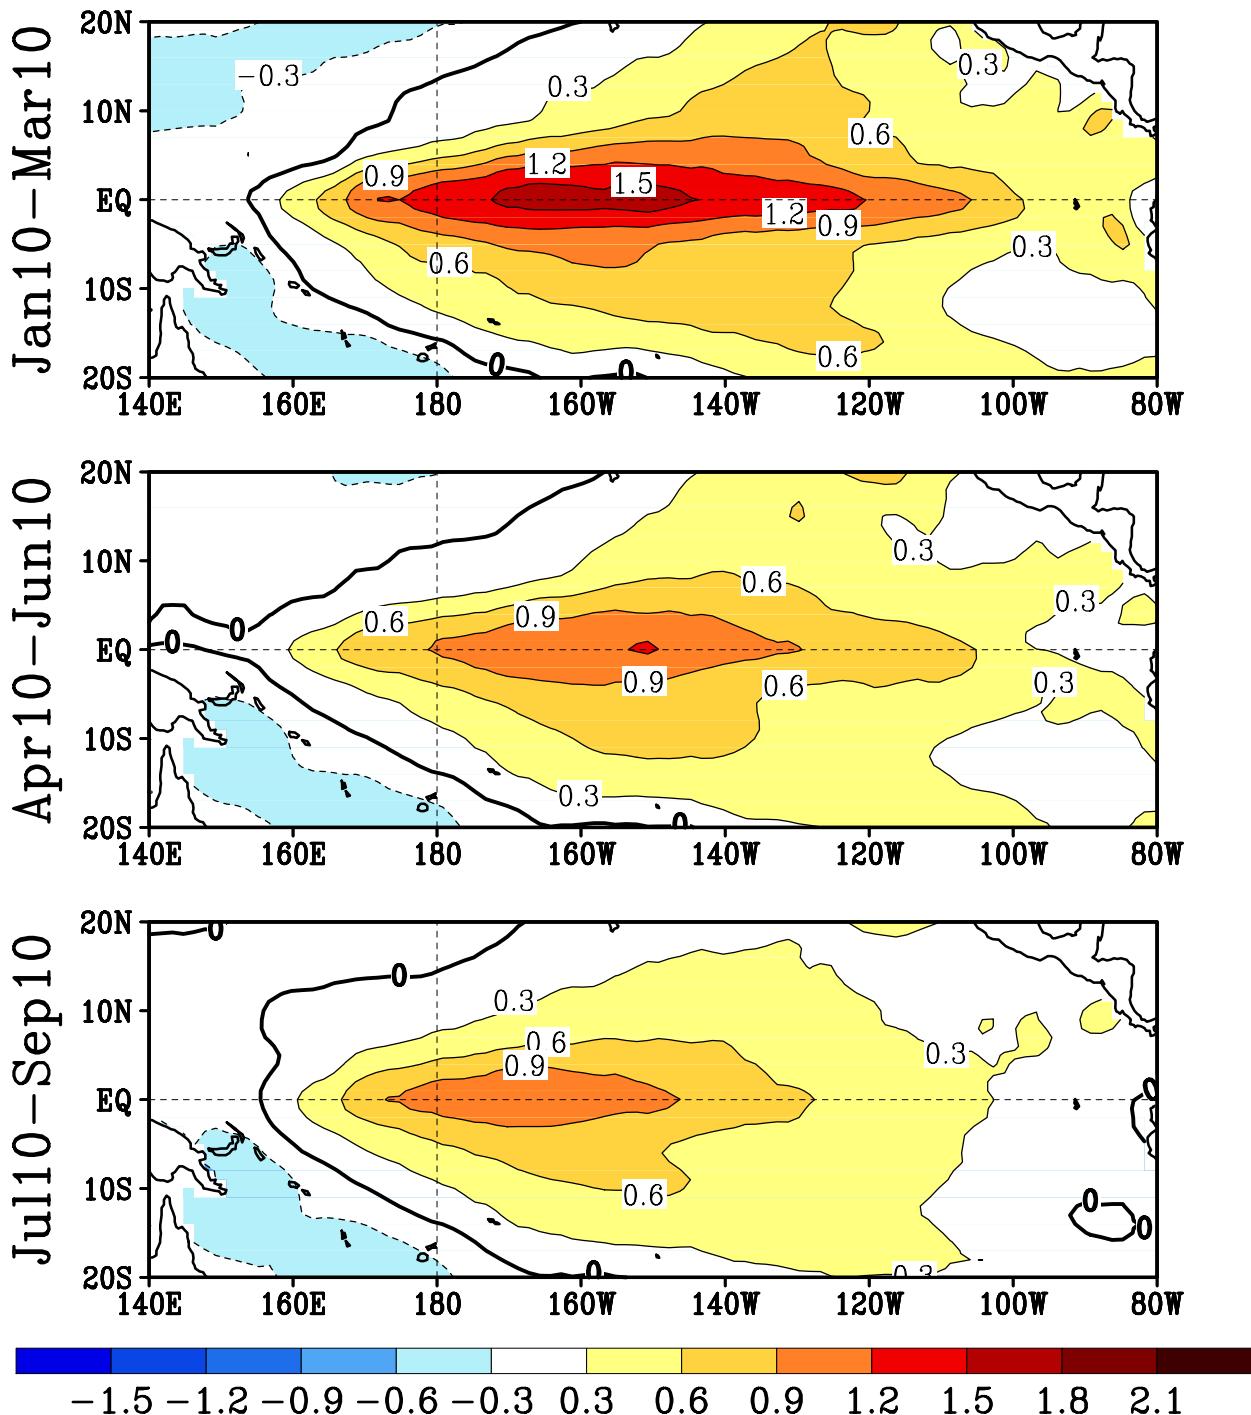

FIGURE F5. Predicted 3-month average sea surface temperature anomalies from the NCEP/CPC Markov model (Xue et al. 2000, *J. Climate*, **13**, 849–871). The forecast is initiated in DEC 2009 . Contour interval is 0.3C and negative anomalies are indicated by dashed contours. Anomalies are calculated relative to the 1971–2000 climatology.

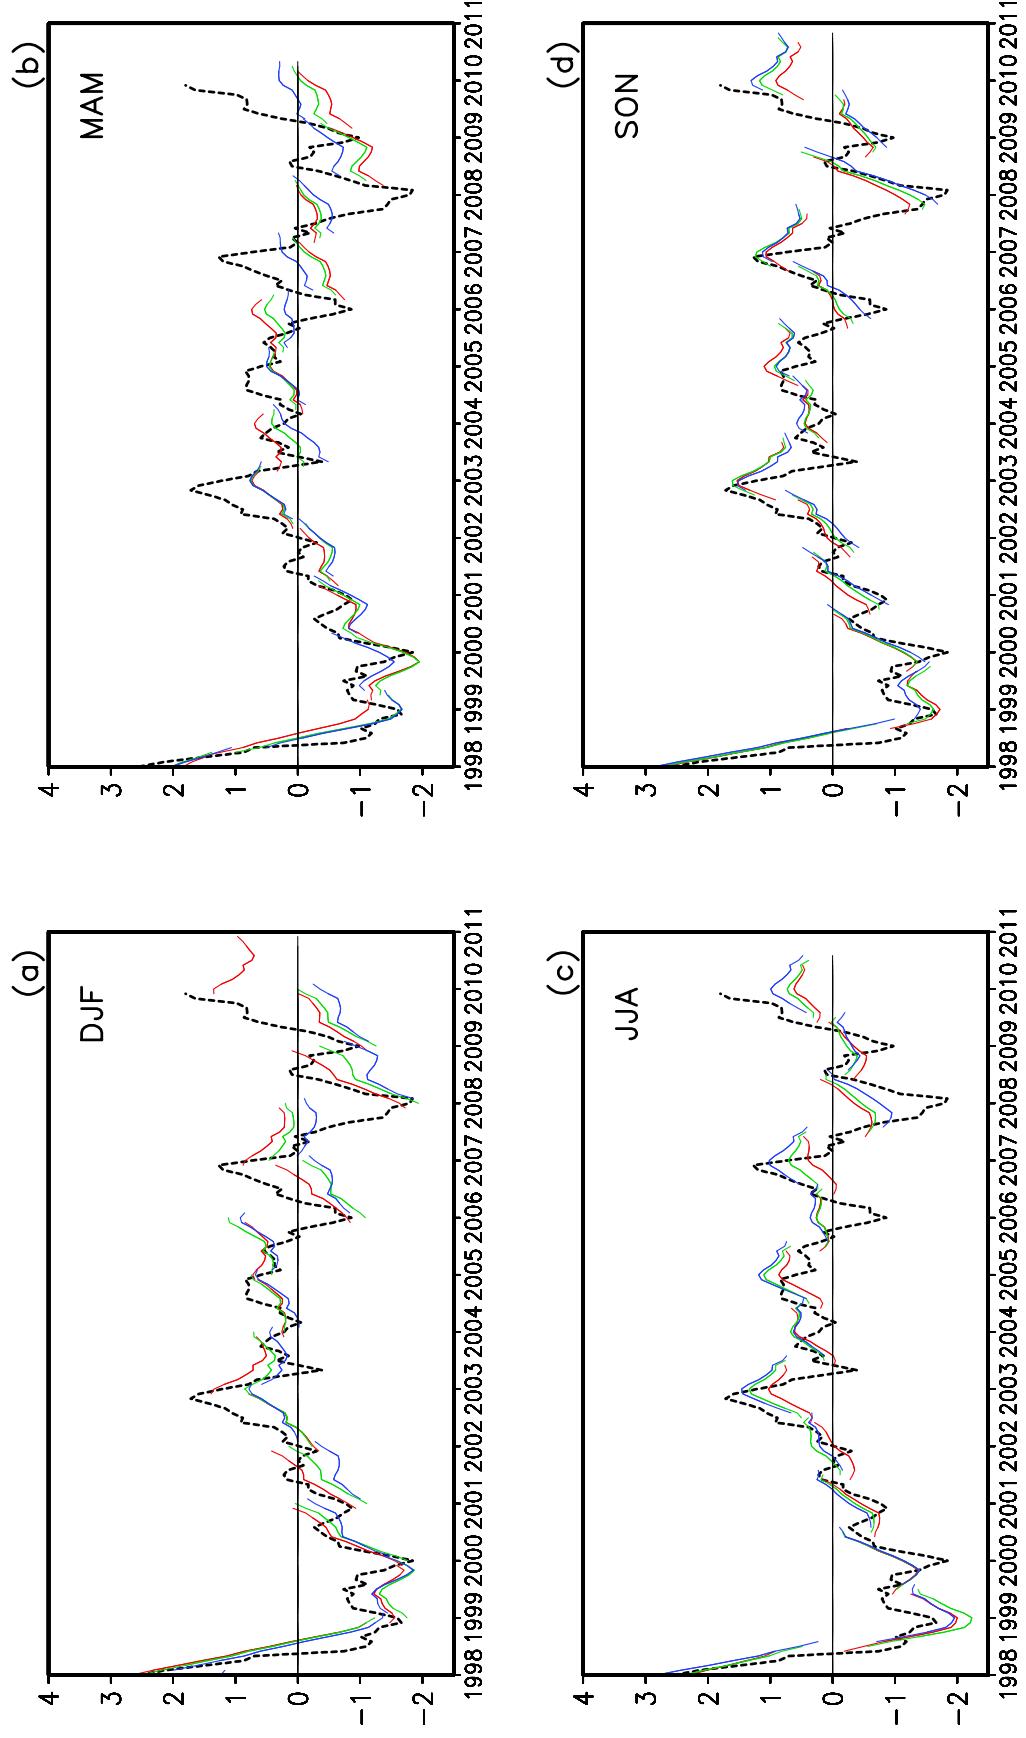

FIGURE F6. Time evolution of observed and predicted SST anomalies in the Niño 3.4 region (up to 12 lead months) by the NCEP/CPC Markov model (Xue et al. 2000, *J. Climate*, **13**, 849–871). Anomalies are calculated relative to the 1971–2000 climatology. Shown in each panel are the forecasts grouped by three consecutive starting months: (a) is for December, January, and February, (b) is for March, April, and May, (c) is for September, October, and November. The observed Niño 3.4 SST anomalies are indicated by the black dashed lines. The Niño 3.4 region spans the east-central equatorial Pacific between 5°N–5°S, 170°W–120°W.

LDEO FORECASTS OF SST AND WIND STRESS ANOMALIES

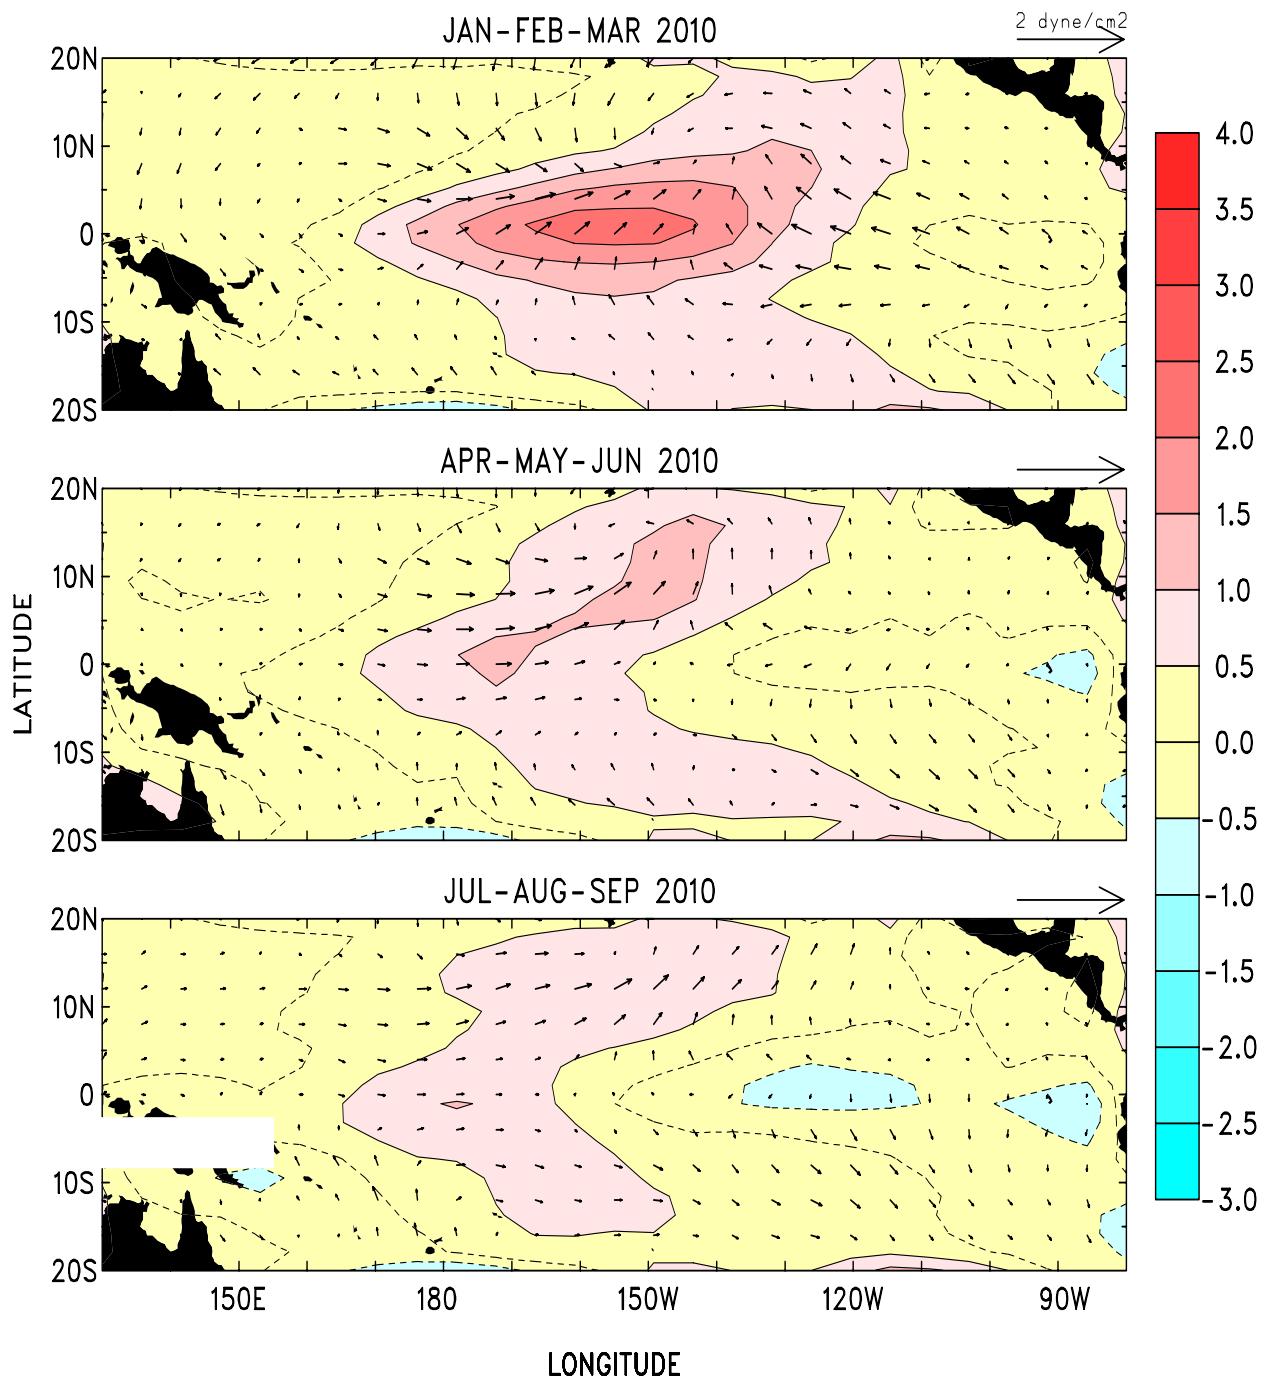

FIGURE F7. Forecasts of the tropical Pacific Predicted SST (shading) and vector wind anomalies for the next 3 seasons based on the LDEO model. Each forecast represents an ensemble average of 3 sets of predictions initialized during the last three consecutive months (see Figure F8).

LDEO FORECASTS OF NIN03

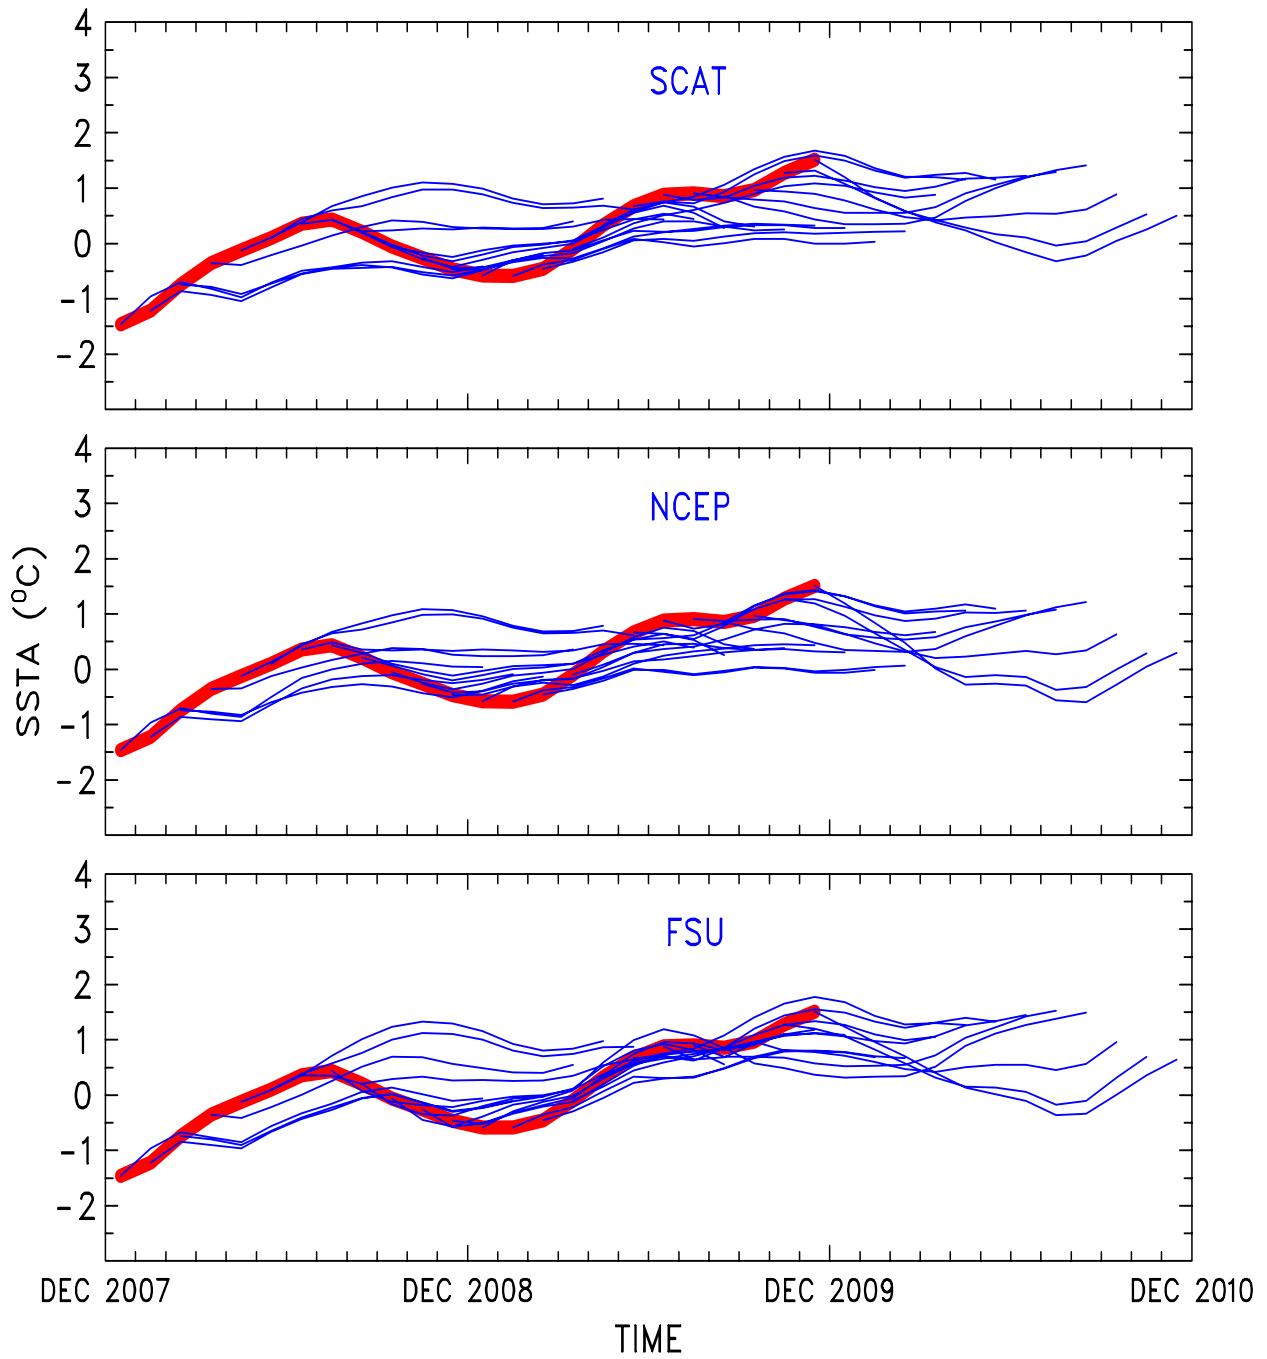

FIGURE F8. LDEO forecasts of SST anomalies for the Nino 3 region using wind stresses obtained from (top) QuikSCAT, (middle) NCEP, and (bottom) Florida State Univ. (FSU), along with SSTs (obtained from NCEP), and sea surface height data (obtained from TOPEX/POSEIDON) data. Each thin blue line represents a 12-month forecast, initialized one month apart for the past 24 months. Observed SST anomalies are indicated by the thick red line. The Nino-3 region spans the eastern equatorial Pacific between 5N-5S, 150W-90W.

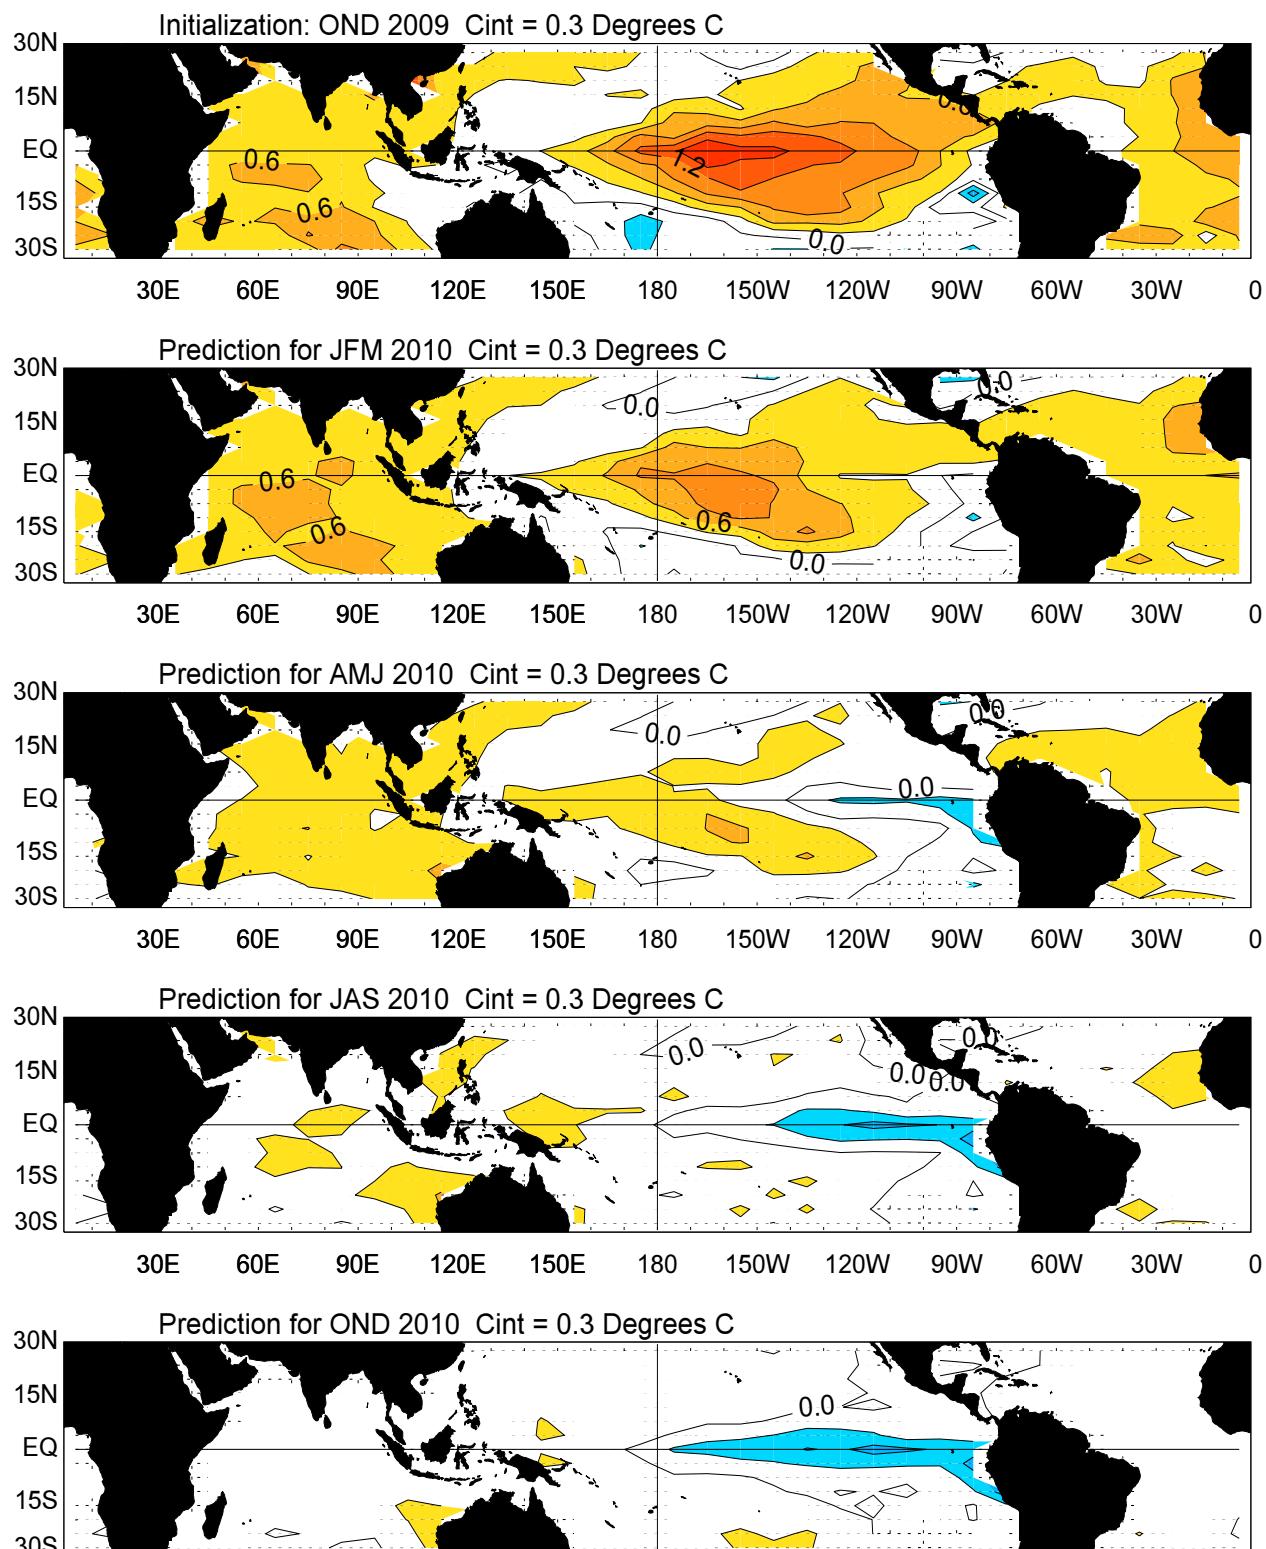

FIGURE F9. Forecast of tropical SST anomalies from the Linear Inverse Modeling technique of Penland and Magorian (1993: *J. Climate*, **6**, 1067-1076). The contour interval is 0.3C. Anomalies are calculated relative to the 1951-2000 climatology and are projected onto 20 leading EOFs.

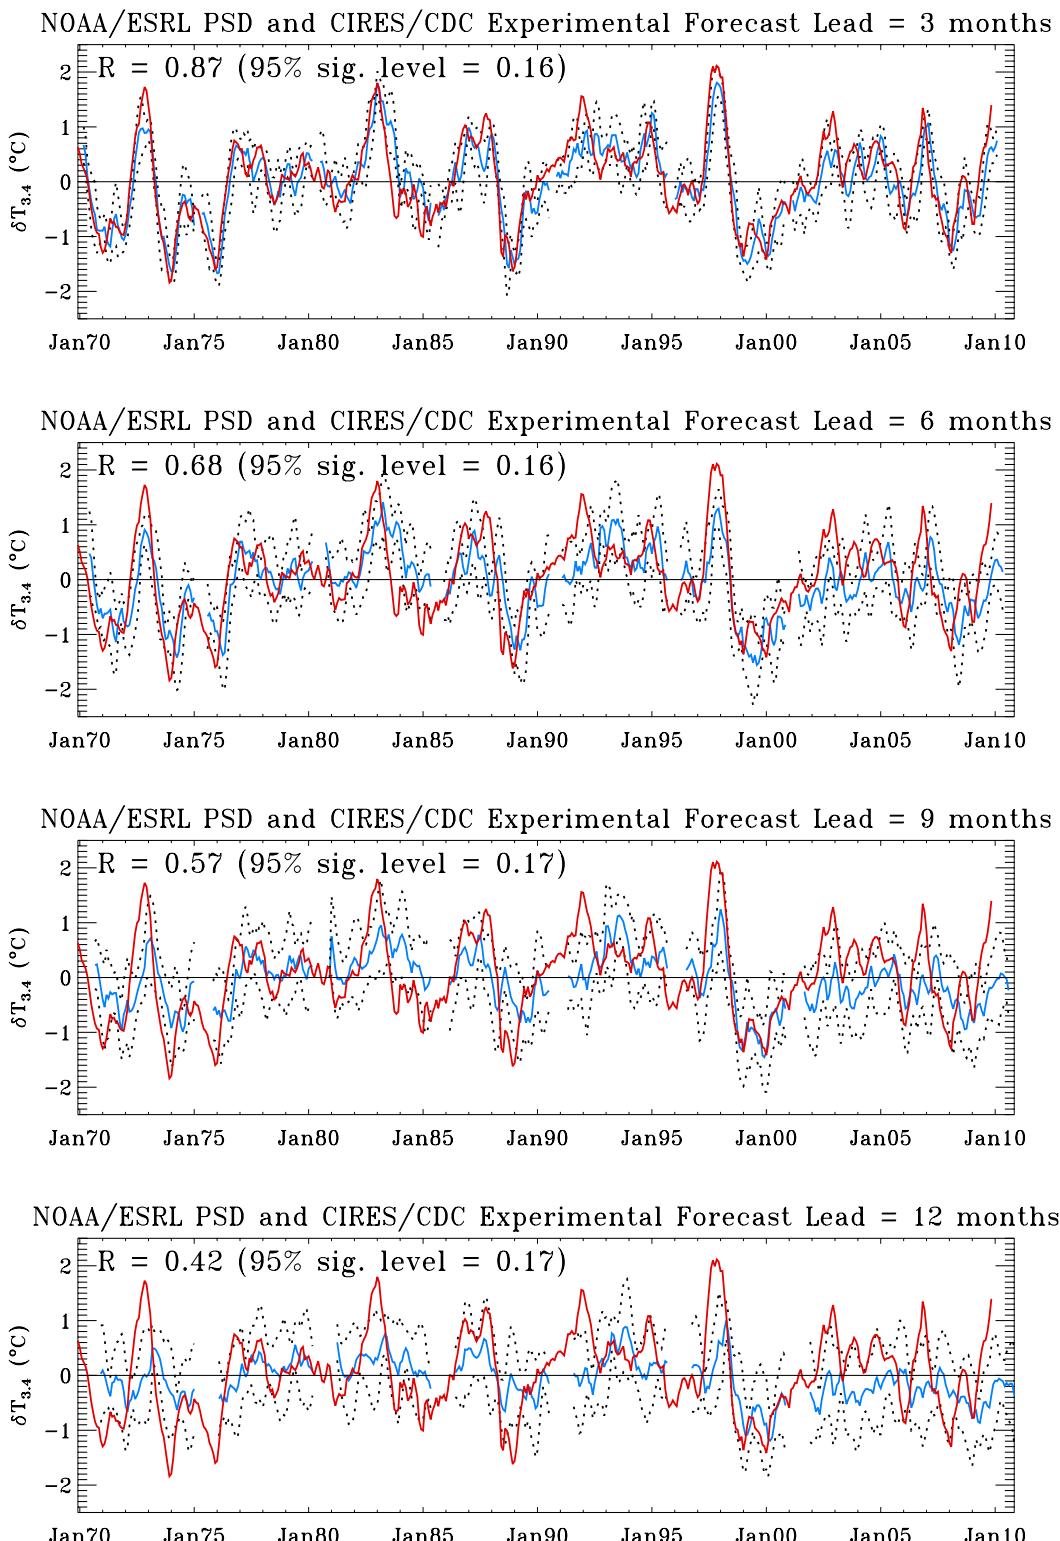

FIGURE F10. Predictions of SST anomalies in the Niño3.4 region (blue line) for leads of three months (top) to 12 months (bottom), from the Linear Inverse Modeling technique of Penland and Magorian (1993: *J. Climate*, **6**, 1067-1076). Observed SST anomalies are indicated by the red line. Anomalies are calculated relative to the 1951-2000 climatology and are projected onto 20 leading EOFs. The Niño 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W.

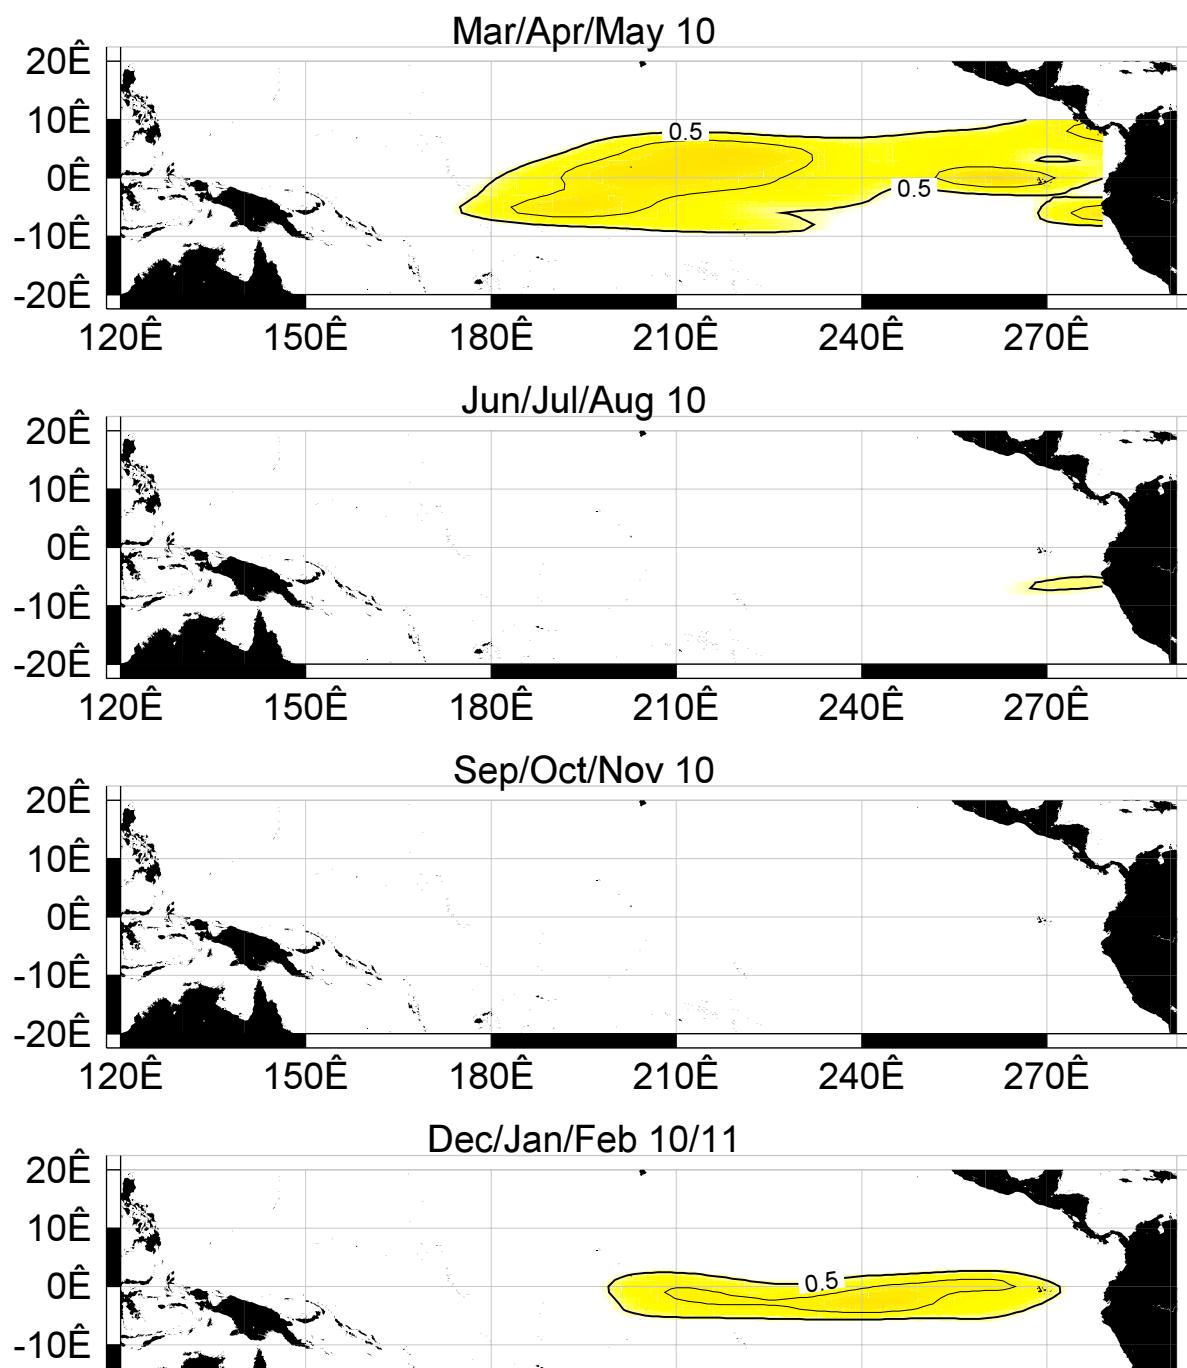

FIGURE F11. SST anomaly forecast for the equatorial Pacific from the Hybrid Coupled Model (HCM) developed by the Scripps Institution of Oceanography and the Max-Plank Institut fuer Meteorologie.

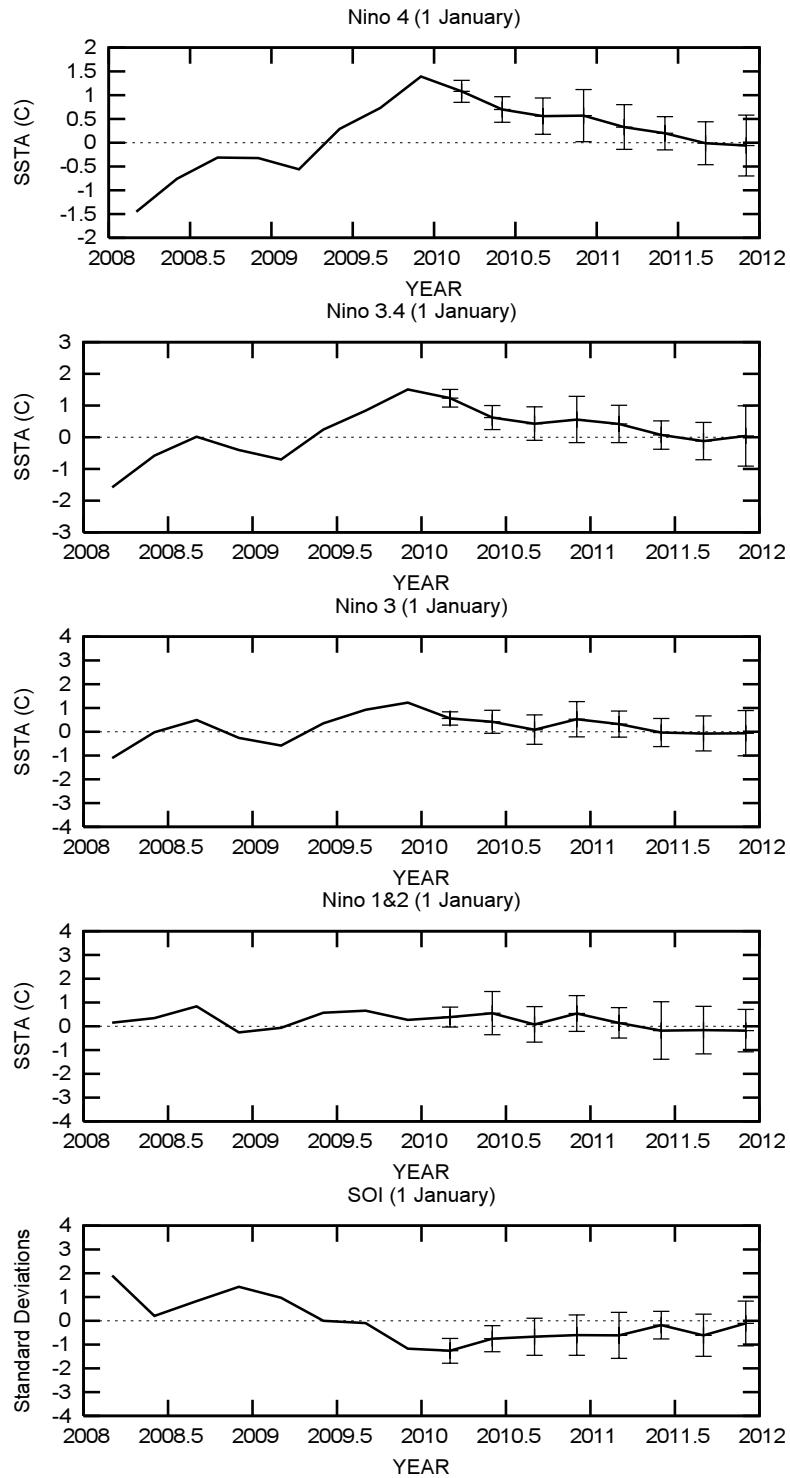

FIGURE F12. ENSO-CLIPER statistical model forecasts of three-month average sea surface temperature anomalies (green lines, deg. C) in (top panel) the Nino 4 region (5N-5S, 160E-150W), (second panel) the Nino 3.4 region (5N-5S, 170W-120W), (third panel) the Nino 3 region (5N-5S, 150W-90W), and (fourth panel) the Nino 1+2 region (0-10S, 90W-80W) (Knaff and Landsea 1997, *Wea. Forecasting*, **12**, 633-652). Bottom panel shows predictions of the three-month standardized Southern Oscillation Index (SOI, green line). Horizontal bars on green line indicate the adjusted root mean square error (RMSE). The Observed three-month average values are indicated by the thick blue line. SST anomalies are departures from the 1971-2000 base period means, and the SOI is calculated from the 1951-1980 base period means.

Model Forecasts of ENSO from Dec 2009

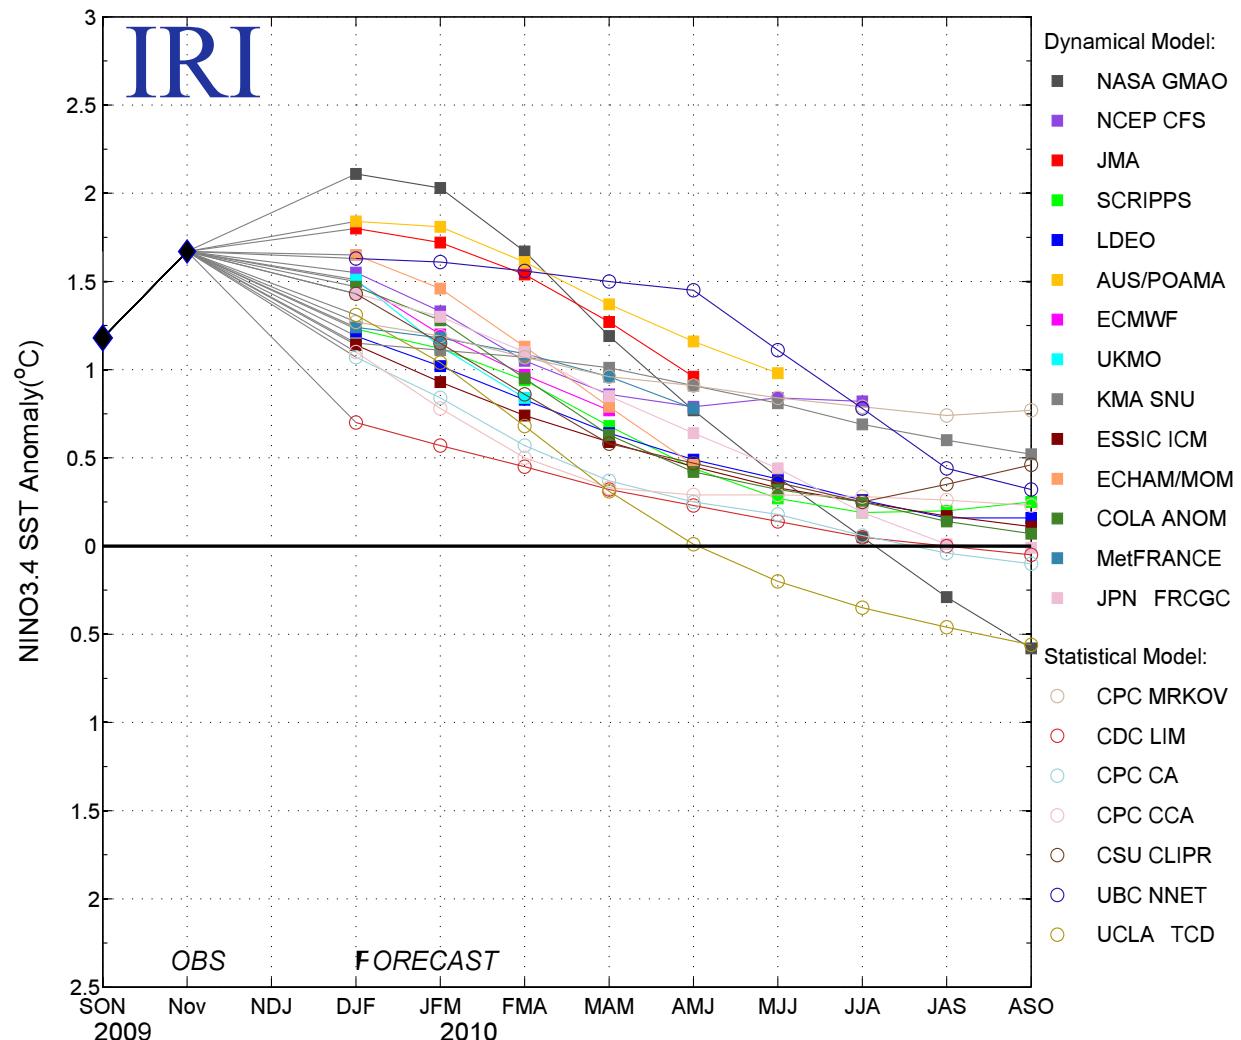

FIGURE F13. Time series of predicted sea surface temperature anomalies for the Nino 3.4 region (deg. C) from various dynamical and statistical models for nine overlapping 3-month periods. The Nino 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W. Figure provided by the International Research Institute (IRI).

Extratropical Highlights – December 2009

1. Northern Hemisphere

The 500-hPa circulation during December featured above-average heights in the polar region and below average heights in the middle latitudes (**Fig. E9**). Regional aspects of this pattern included strong ridges in western North America and Greenland, and amplified troughs in central North America, across the central North Atlantic and central Europe, and central Siberia. This overall pattern reflected the strongest negative phase (-2.4) of the Arctic Oscillation (AO) for any December since 1950 (**Fig. A2.1**). Over the Atlantic sector this pattern produced the strongest negative phase (tied with 1963) of the North Atlantic Oscillation (-1.9) since 1950.

Over the central and subtropical Pacific Ocean, the circulation also reflected a strong El Niño influence (**Fig. T18**). Typical El Niño-related features during December included anticyclonic circulation anomalies over the central and eastern subtropical Pacific, and cyclonic circulation anomalies (**Fig. T22**) and below average heights (**Fig. E9**) across the central extratropical North Pacific. These conditions were associated with an eastward extension of the East Asian jet stream, an eastward shift of the jet exit region to well east of the date line, and a southward shift of the jet axis toward the southwestern U.S. (**Fig. T21**).

The main temperature signals during December included above average temperatures in Alaska, and well below average temperatures in western North America and central Siberia (**Fig. E1**). The main precipitation signals included above-average totals across the southern tier of the United States and southern Europe, and below-average totals in much of Canada (**Fig. E3**).

a. North Pacific/ North America

A strong El Niño and a record negative phase of the AO both influenced conditions across the North Pacific Ocean and North America during December. El Niño is well known to influence the structure and location of the East Asian jet stream, which in turn affects the circulation, temperature, and precipitation patterns across the extratropical North Pacific and North America. Normally, the core of the East Asian jet stream is located well west of the date line, and the jet exit region is centered near the date line. During El Niño, enhanced convection over the central equatorial Pacific (**Fig. T25**) acts to strengthen and extend eastward the subtropical ridge (**Fig. T22**), resulting in 1) an eastward extension of the East Asian jet core, 2) a shift of the jet exit region toward the eastern Pacific, and 3) a southward shift of the jet axis toward the southwestern U.S. (**Fig. T21**). Also, an anomalous jet entrance region is produced in the vicinity of the date line, and the resulting ageostrophic circulation leads to below average heights and anomalous cyclonic vorticity north of the jet core (**Figs. E9, T22**).

These conditions typically produce a more zonal flow across North America and a weaker Hudson Bay trough, both of which lead to above average temperatures in Canada and the northern United States. However, this signal was absent during December, largely due to the record negative phase of the AO.

This AO was associated with an amplified ridge in western North America, and with a westward shift of the mean Hudson Bay trough axis to the central United States. The enhanced meridional flow led to well below average temperatures across the western half of North America (**Fig. E1**). It also contributed to a continuation of above average precipitation across the eastern United States (**Fig. E5**), with some areas recording totals in the upper 90th percentile of occurrences (**Fig. E2**).

b. Eurasia

The 500-hPa circulation during December reflected a strong negative phase of the NAO, which occurred in association with the hemispheric-scale AO. This pattern featured positive height anomalies across Greenland and the polar region, and negative height anomalies across the central North Atlantic and central Europe (**Fig. E9**). These conditions reflected a strong ridge at high latitudes, and a pronounced southward shift of the mean jet axis to southern Europe (**Fig. T21**). A main impact from these conditions was strong northerly flow and well below average temperatures (exceeding -5°C) in central Siberia, with departures throughout the region in the lowest 10th percentile of occurrences (**Fig. E1**). Another impact was increased storminess and above average precipitation across southern Europe and southwestern Russia (**Fig. E3**).

2. Southern Hemisphere

The 500-hPa circulation during December featured generally below average heights at high latitudes and an anomalous zonal wave-3 pattern in the middle latitudes (**Fig. E15**). Regional aspects of this pattern include above average heights over the central South Pacific and South Atlantic Oceans and in the region south of Australia. The main temperature anomalies during the month included warmer than average conditions in southern Africa, southeastern Brazil, and large portions of coastal Australia (**Fig. E1**). The main precipitation signals reflected above average totals in central and southeastern South America and below average totals in southeastern Africa (**Fig. E3**).

The South African rainy season lasts from October to April. For the 2009-10 season, precipitation was near-average during October, above average during November, and below average during December (**Fig. E4**). Rainfall is typically below average in this region during El Niño.

TABLE E1-Standardized amplitudes of selected Northern Hemisphere teleconnection patterns for the most recent thirteen months (computational procedures are described in Fig. E7). Pattern names and abbreviations are North Atlantic Oscillation (NAO); East Atlantic pattern (EA); West Pacific pattern (WP); East Pacific - North Pacific pattern (EP-NP); Pacific/North American pattern (PNA); Tropical/Northern Hemisphere pattern (TNH);East Atlantic/Western Russia pattern (EATL/WRUS)-called Eurasia-2 pattern by Barnston and Livezey, 1987, *Mon. Wea. Rev.*, **115**, 1083-1126; Scandanavia pattern (SCAND-called Eurasia-1 pattern by Barnston and Livezey 1987); and Polar Eurasia pattern (POLEUR). No value is plotted for calendar months in which the pattern does not appear as a leading mode.

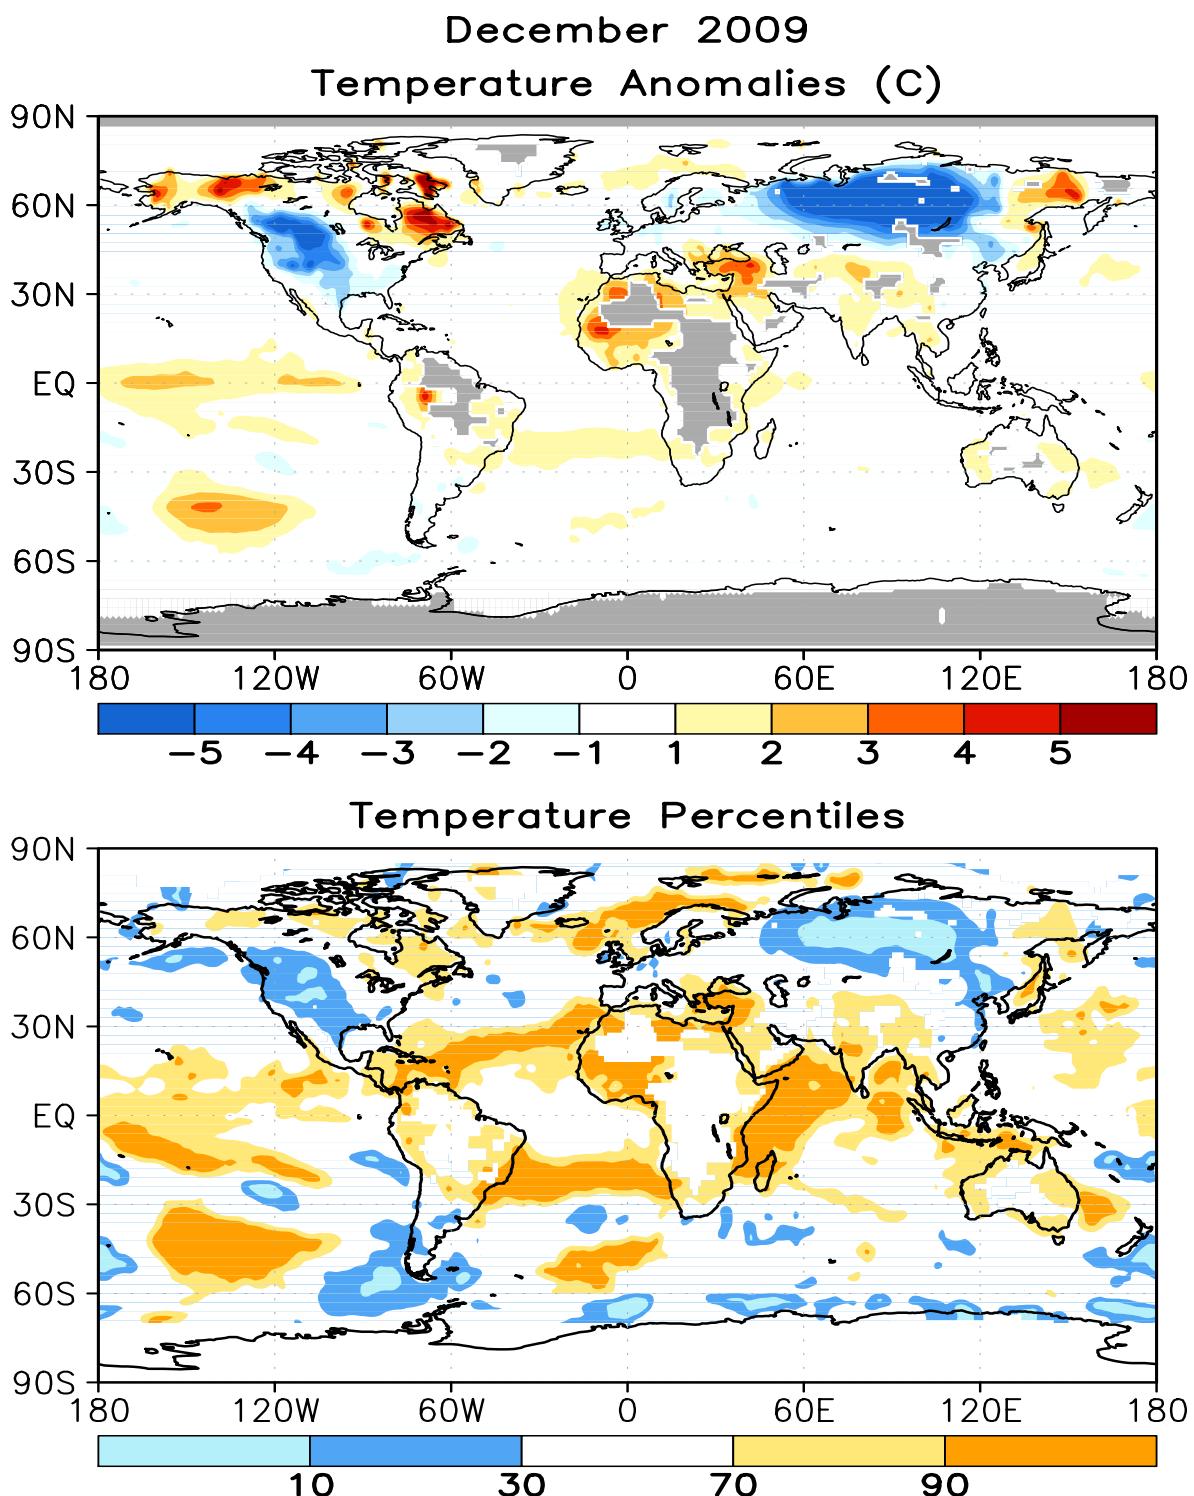

FIGURE E1. Surface temperature anomalies ($^{\circ}\text{C}$, top) and surface temperature expressed as percentiles of the normal (Gaussian) distribution fit to the 1971–2000 base period data (bottom) for DEC 2009. Analysis is based on station data over land and on SST data over the oceans (top). Anomalies for station data are departures from the 1971–2000 base period means, while SST anomalies are departures from the 1971–2000 adjusted OI climatology. (Smith and Reynolds 1998, *J. Climate*, **11**, 3320–3323). Regions with insufficient data for analysis in both figures are indicated by shading in the top figure only.

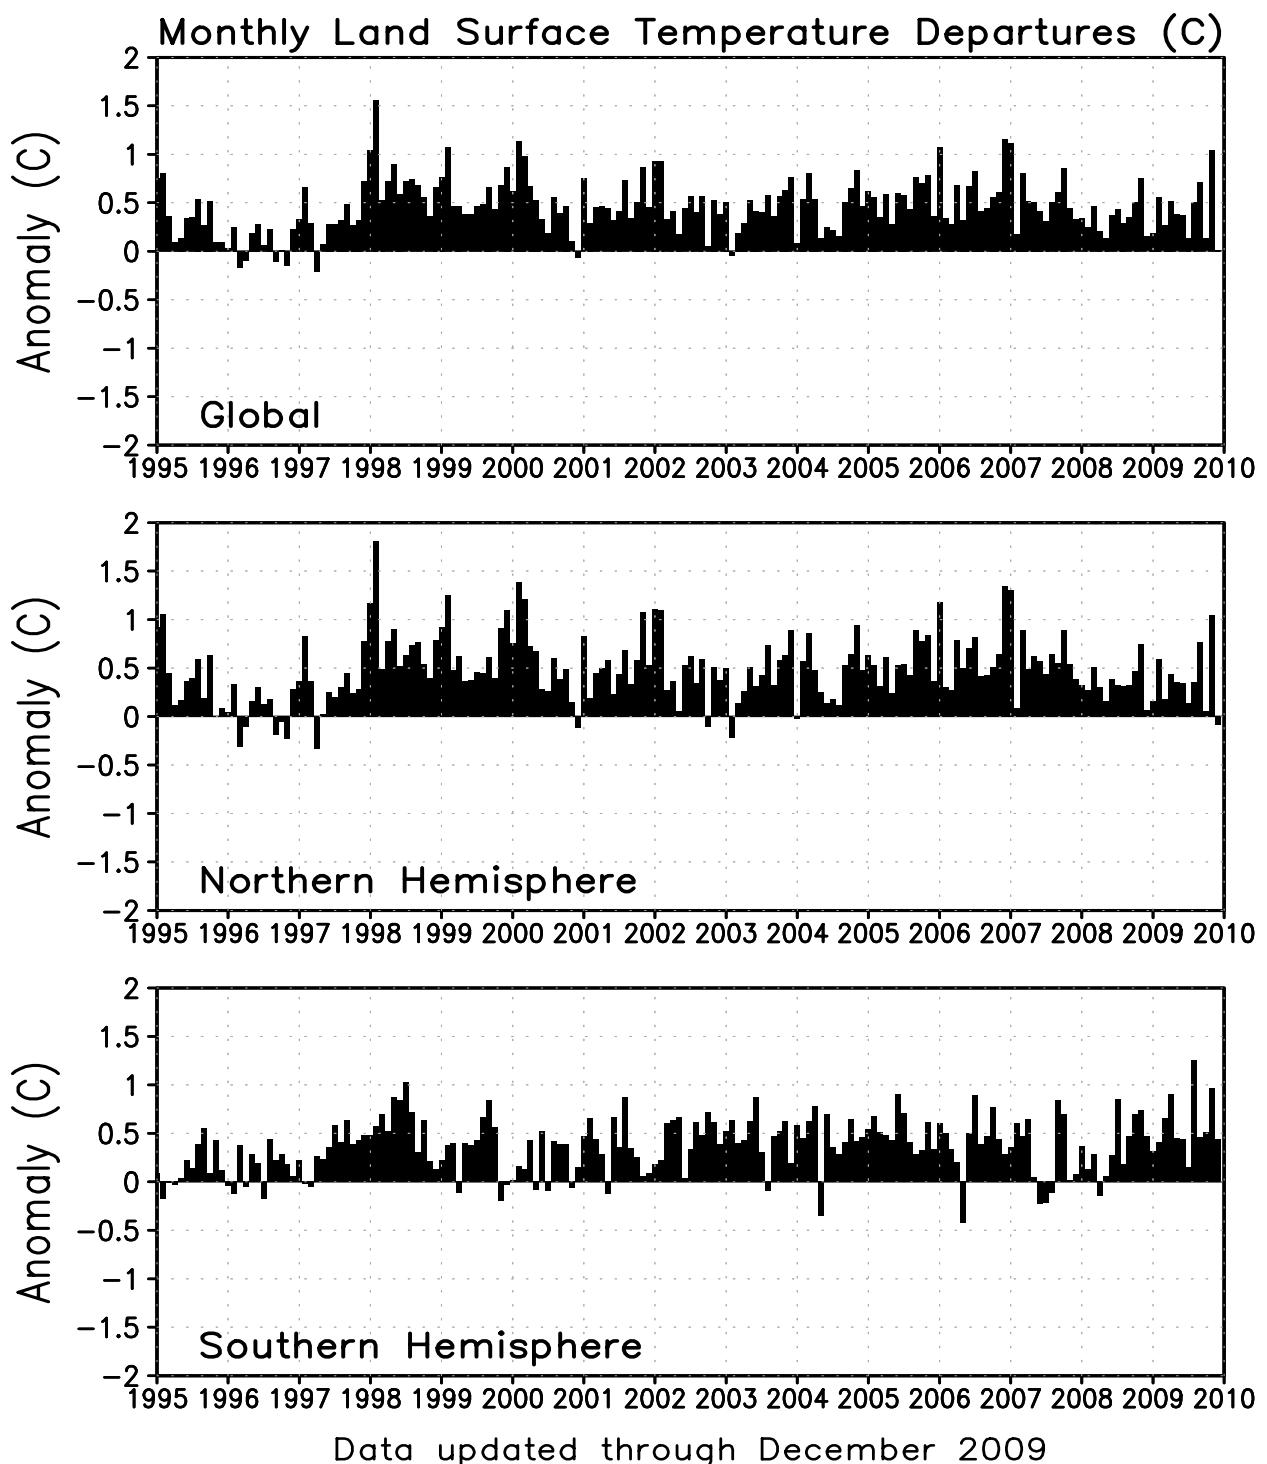

FIGURE E2. Monthly global (top), Northern Hemisphere (middle), and Southern Hemisphere (bottom) surface temperature anomalies (land only, $^{\circ}\text{C}$) from January 1990 - present, computed as departures from the 1971–2000 base period means.

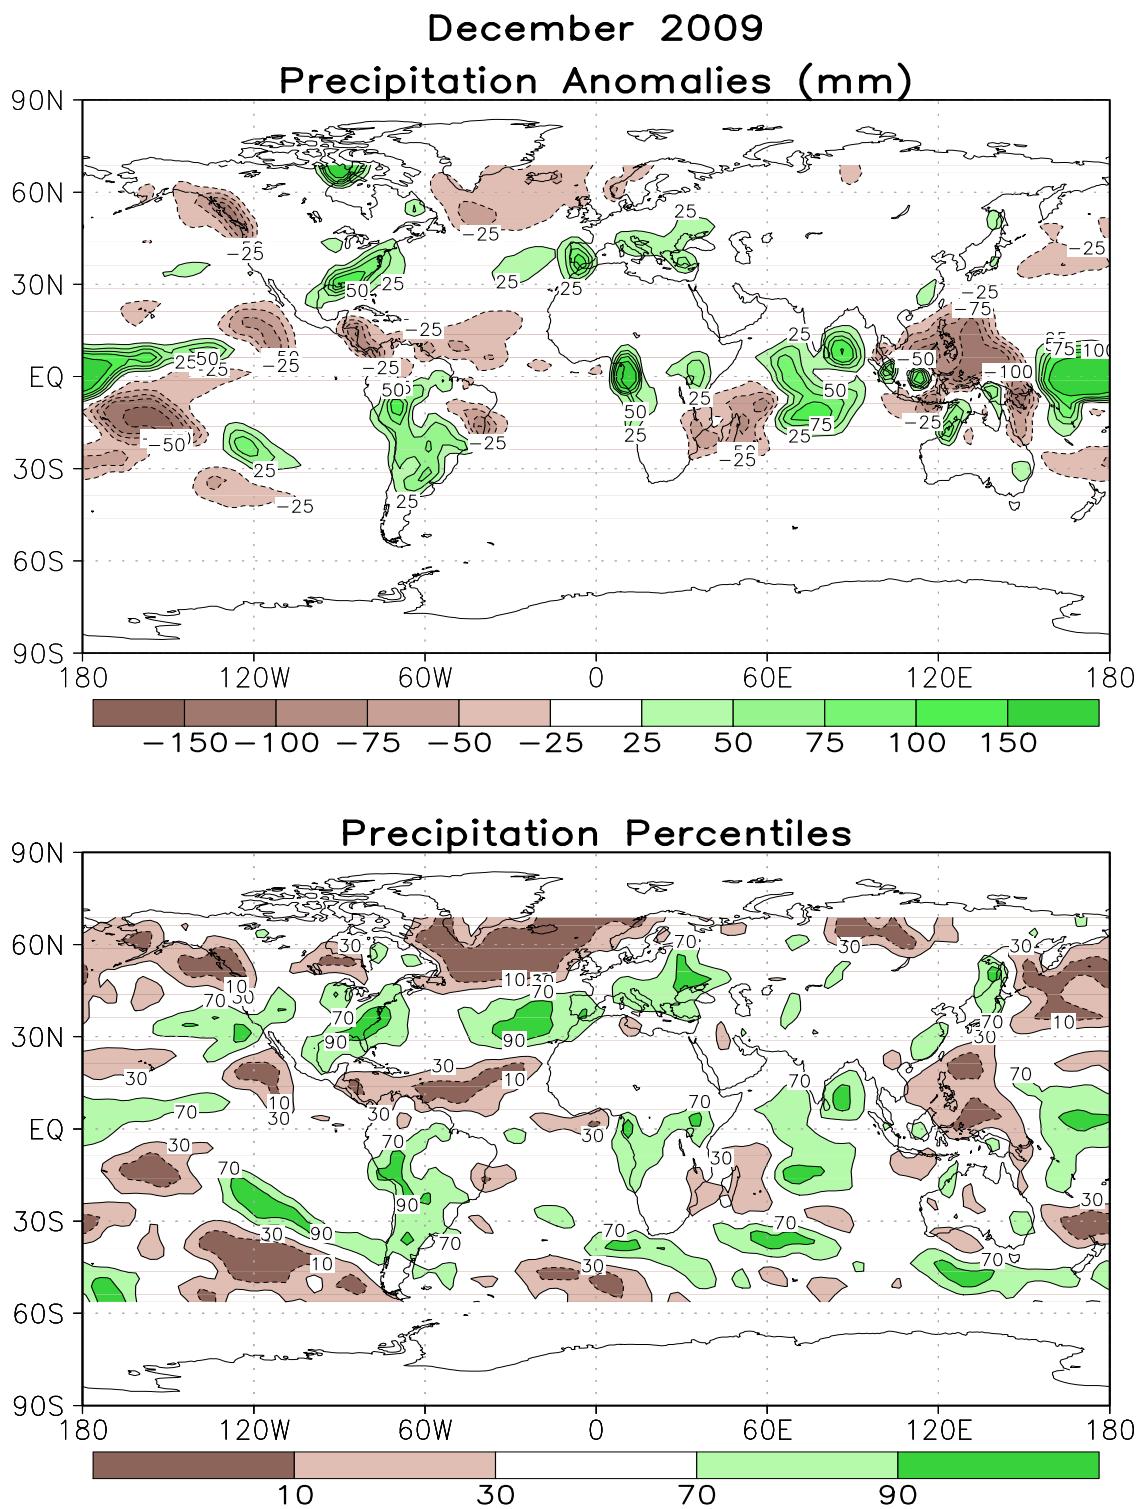

FIGURE E3. Anomalous precipitation (mm, top) and precipitation percentiles based on a Gamma distribution fit to the 1979–2000 base period data (bottom) for DEC 2009. Data are obtained from a merge of raingauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, **12**, 3335–3342). Contours are drawn at 200, 100, 50, 25, -25, -50, -100, and -200 mm in top panel. Percentiles are not plotted in regions where mean monthly precipitation is <5mm/month.

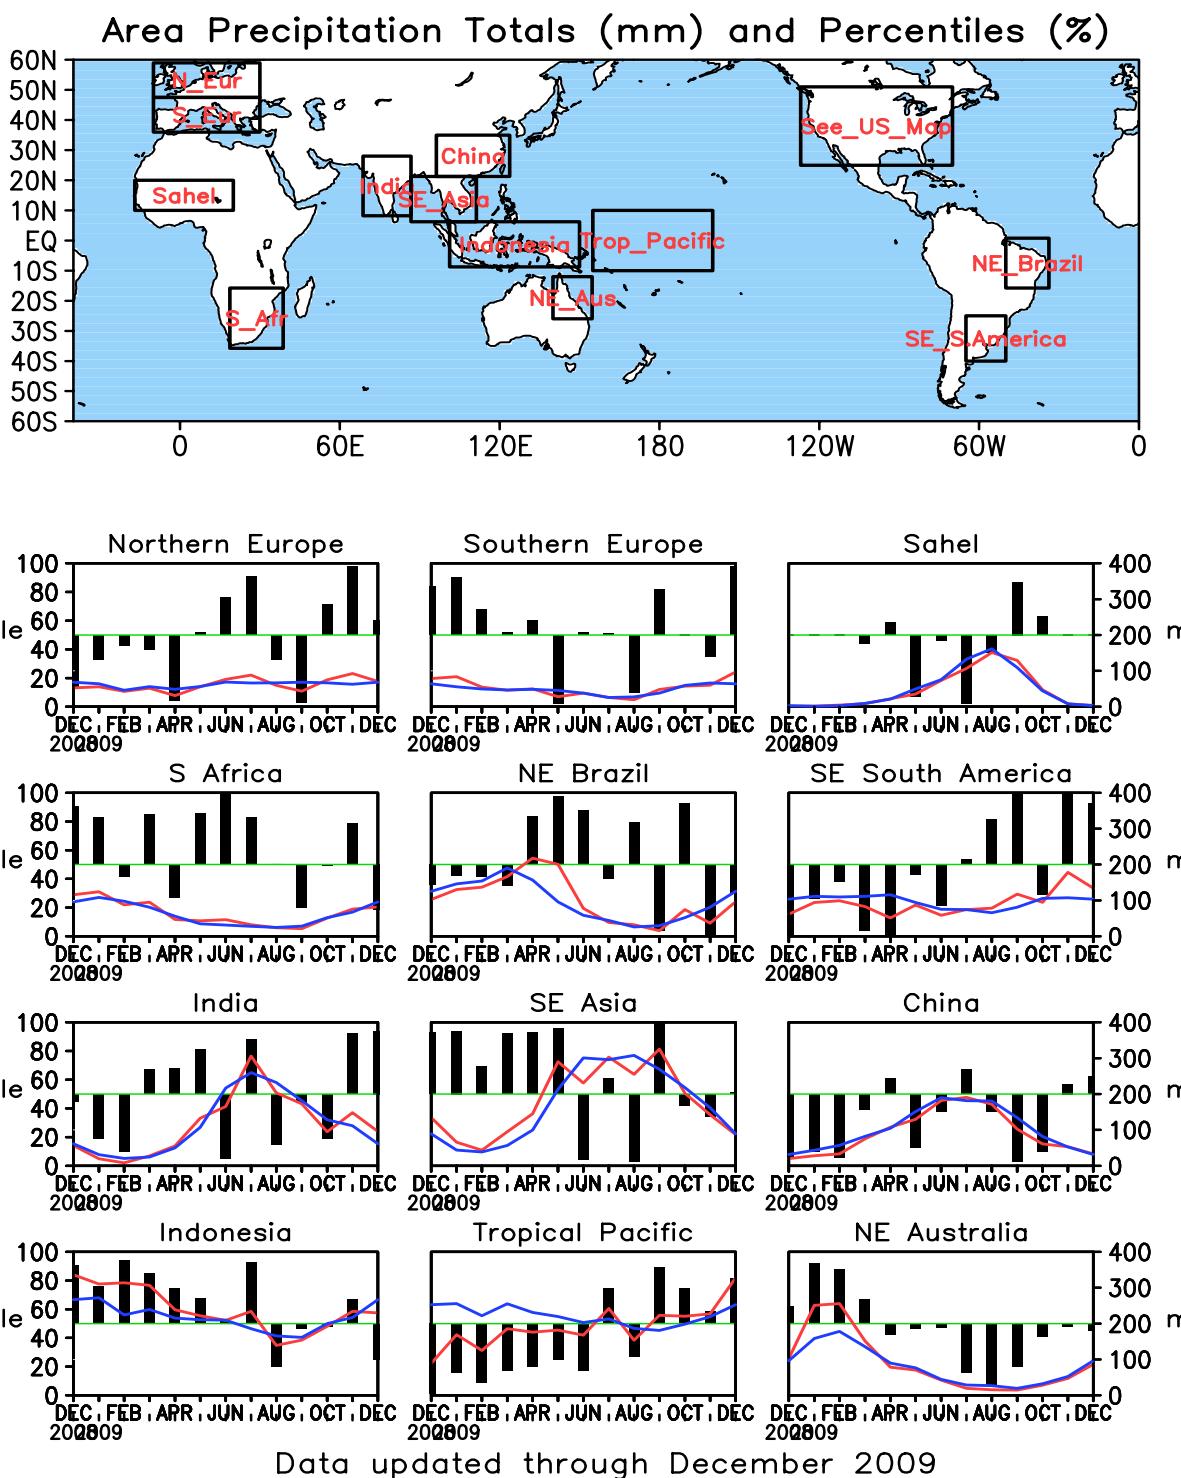

FIGURE E4. Areal estimates of monthly mean precipitation amounts (mm, solid lines) and precipitation percentiles (%, bars) for the most recent 13 months obtained from a merge of raingauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, **12**, 3335–3342). The monthly precipitation climatology (mm, dashed lines) is from the 1979–2000 base period monthly means. Monthly percentiles are not shown if the monthly mean is less than 5 mm.

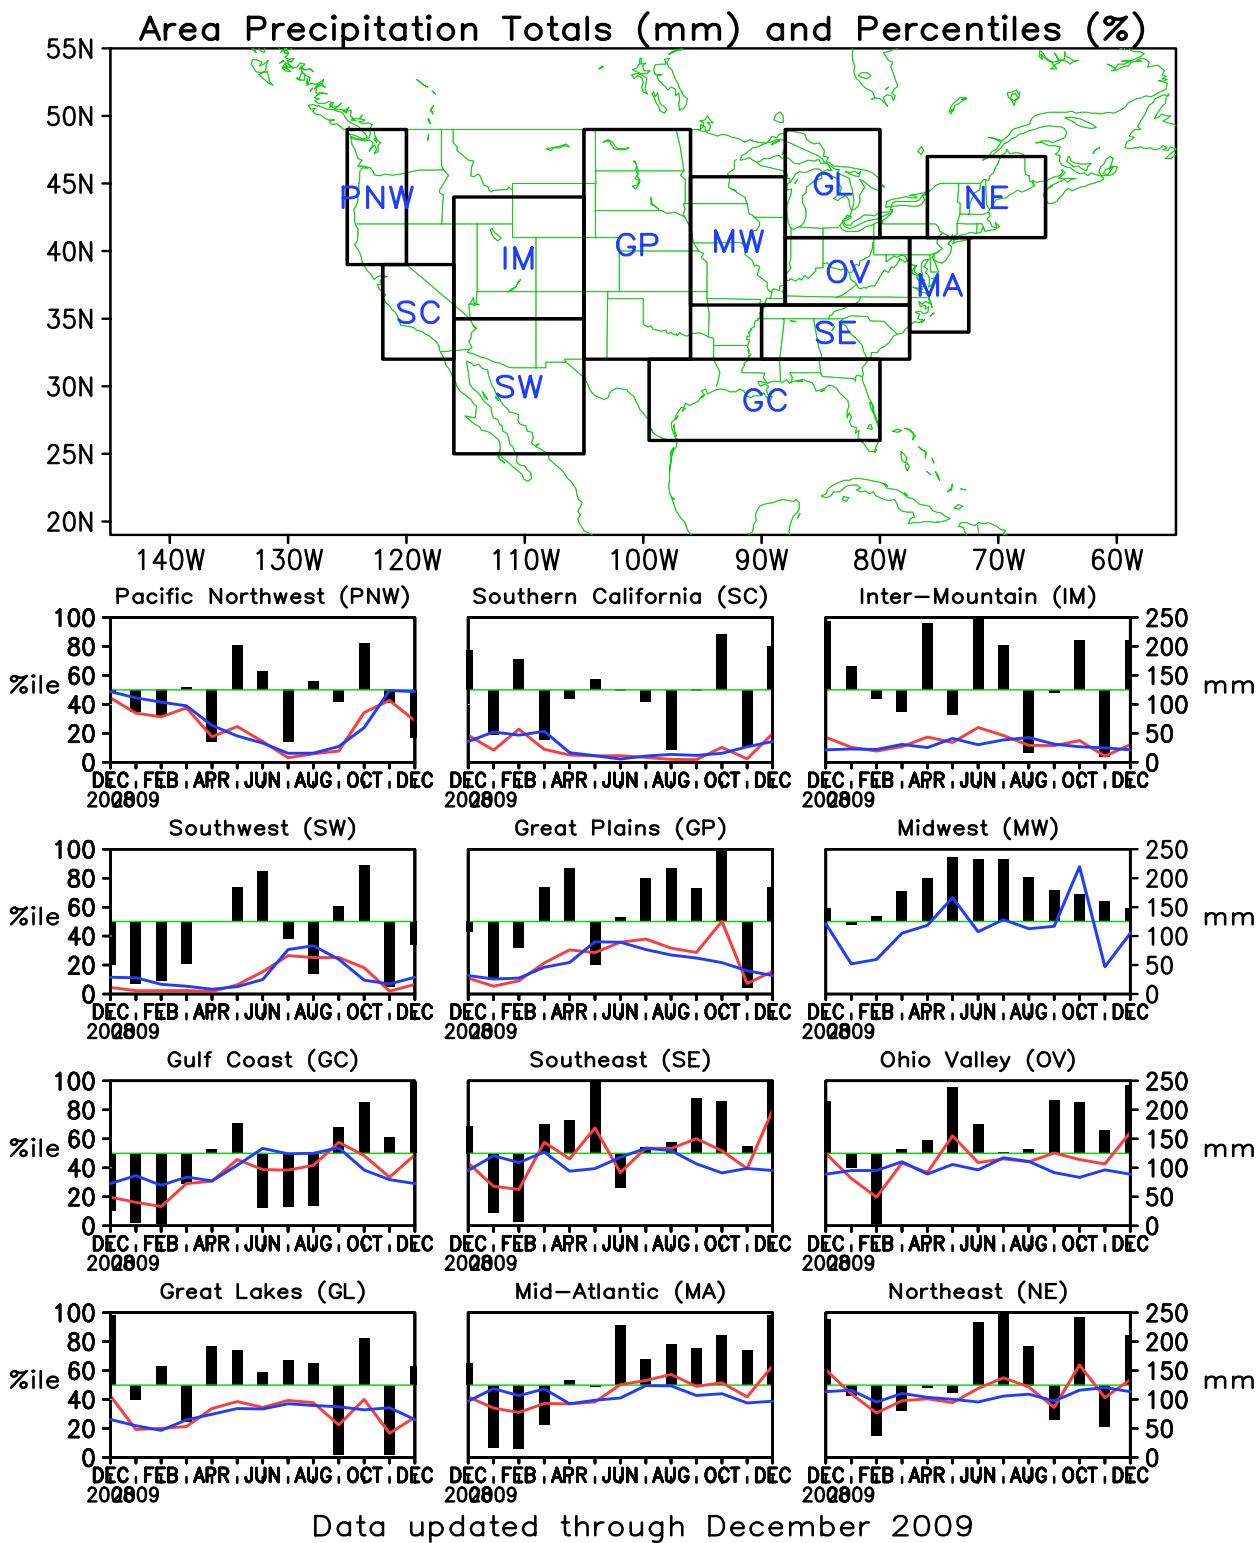

FIGURE E5. Areal estimates of monthly mean precipitation amounts (mm, solid lines) and precipitation percentiles (%, bars) for the most recent 13 months obtained from a merge of raingauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, **12**, 3335–3342). The monthly precipitation climatology (mm, dashed lines) is from the 1979–2000 base period monthly means. Monthly percentiles are not shown if the monthly mean is less than 5 mm.

Monthly Accumulation -- December, 2009

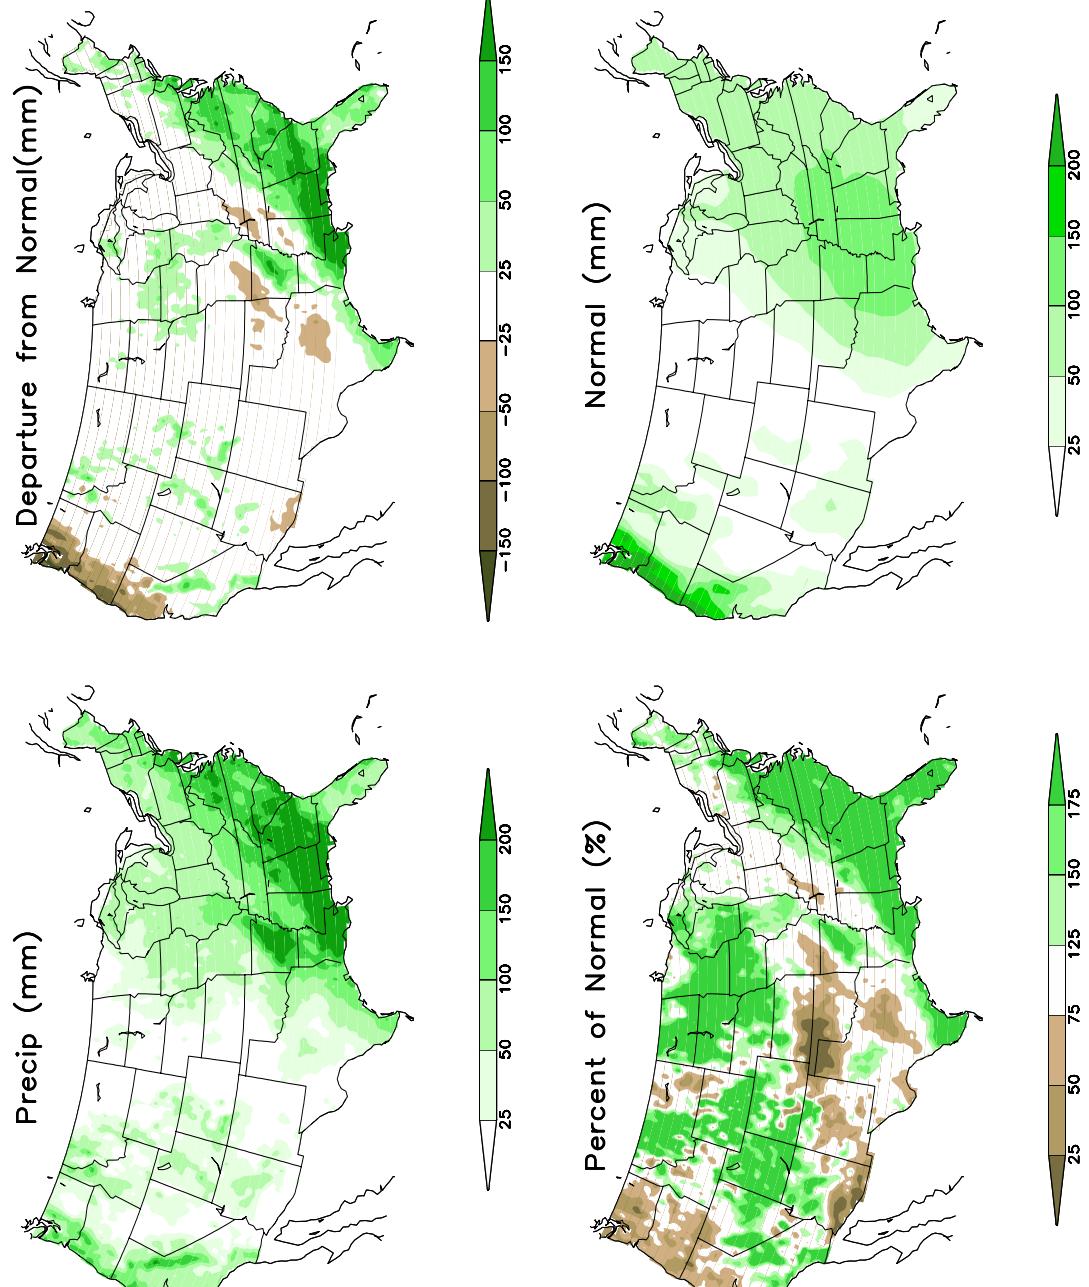

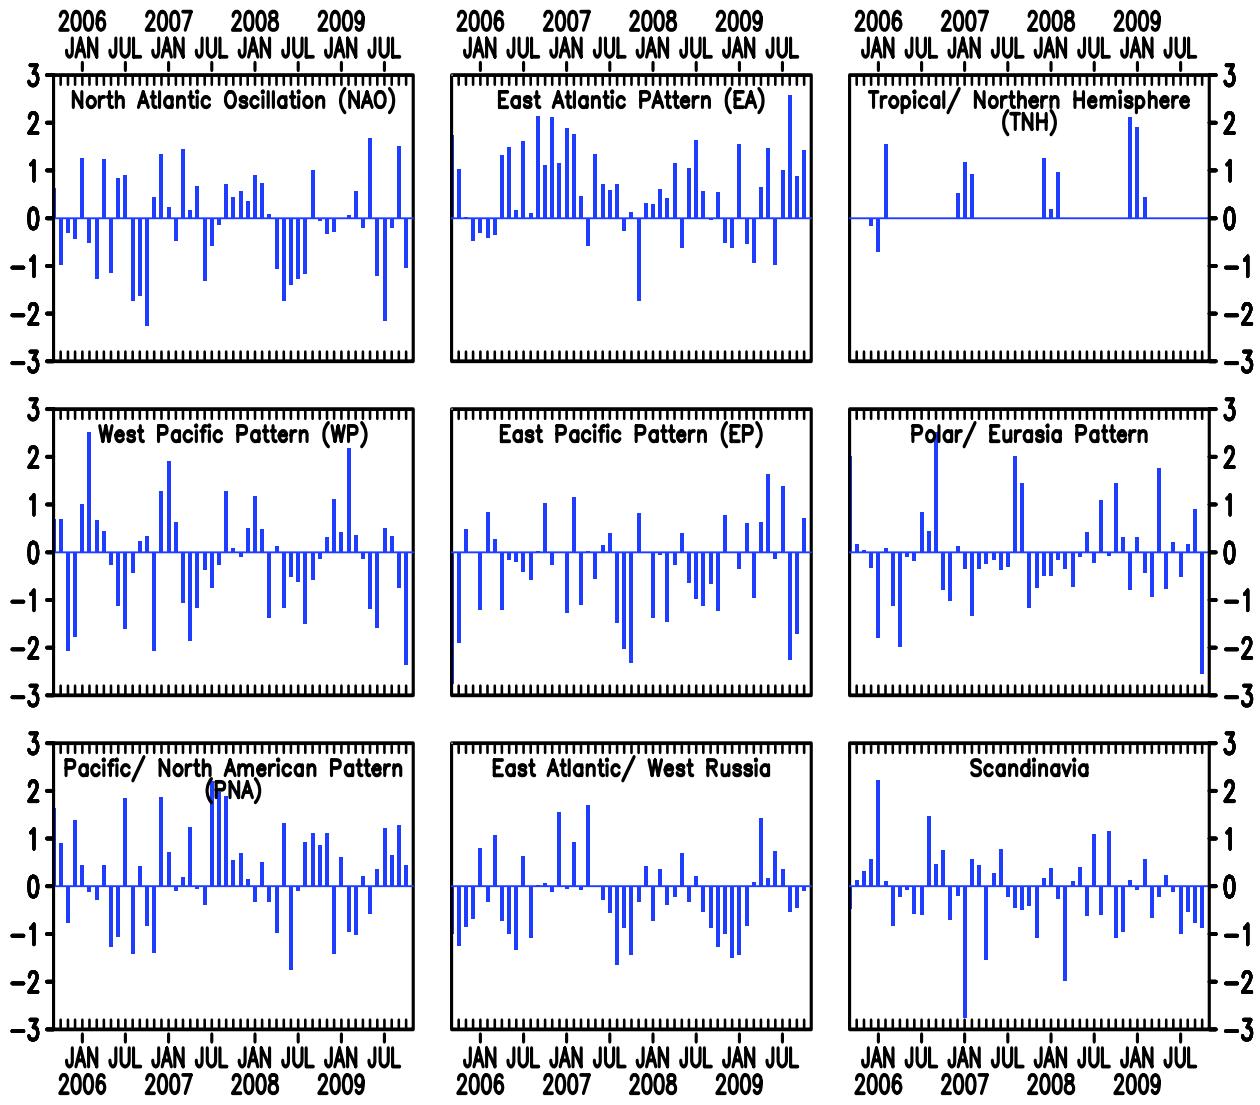

FIGURE E6. Observed precipitation (upper left), departure from average (lower left), and percent of average (upper right), percent of average (lower right), and average precipitation (lower right) for DEC 2009. The units are given on each panel. Base period for averages is 1971–2000. Results are based on CPC's U.S. daily precipitation analysis, which is available at <http://www.cpc.ncep.noaa.gov/products/precip/realtime>.

Monthly Teleconnection Indices

Data updated through October 2009

FIGURE E7. Standardized monthly Northern Hemisphere teleconnection indices. The teleconnection patterns are calculated from a Rotated Principal Component Analysis (RPCA) applied to monthly standardized 500-hPa height anomalies during January 1950 – December 2000. To obtain these patterns, ten leading un-rotated modes are first calculated for each calendar month by using the monthly height anomaly fields for the three-month period centered on that month: [i.e., The July modes are calculated from the June, July, and August standardized monthly anomalies]. A Varimax spatial rotation of the ten leading un-rotated modes for each calendar month results in 120 rotated modes (12 months x 10 modes per month) that yield ten primary teleconnection patterns. The teleconnection indices are calculated by first projecting the standardized monthly anomalies onto the teleconnection patterns corresponding to that month (eight or nine teleconnection patterns are seen in each calendar month). The indices are then solved for simultaneously using a Least-Squares approach. In this approach, the indices are the solution to the Least-Squares system of equations which explains the maximum spatial structure of the observed height anomaly field during the month. The indices are then standardized for each pattern and calendar month independently. No index value exists when the teleconnection pattern does not appear as one of the ten leading rotated EOF's valid for that month.

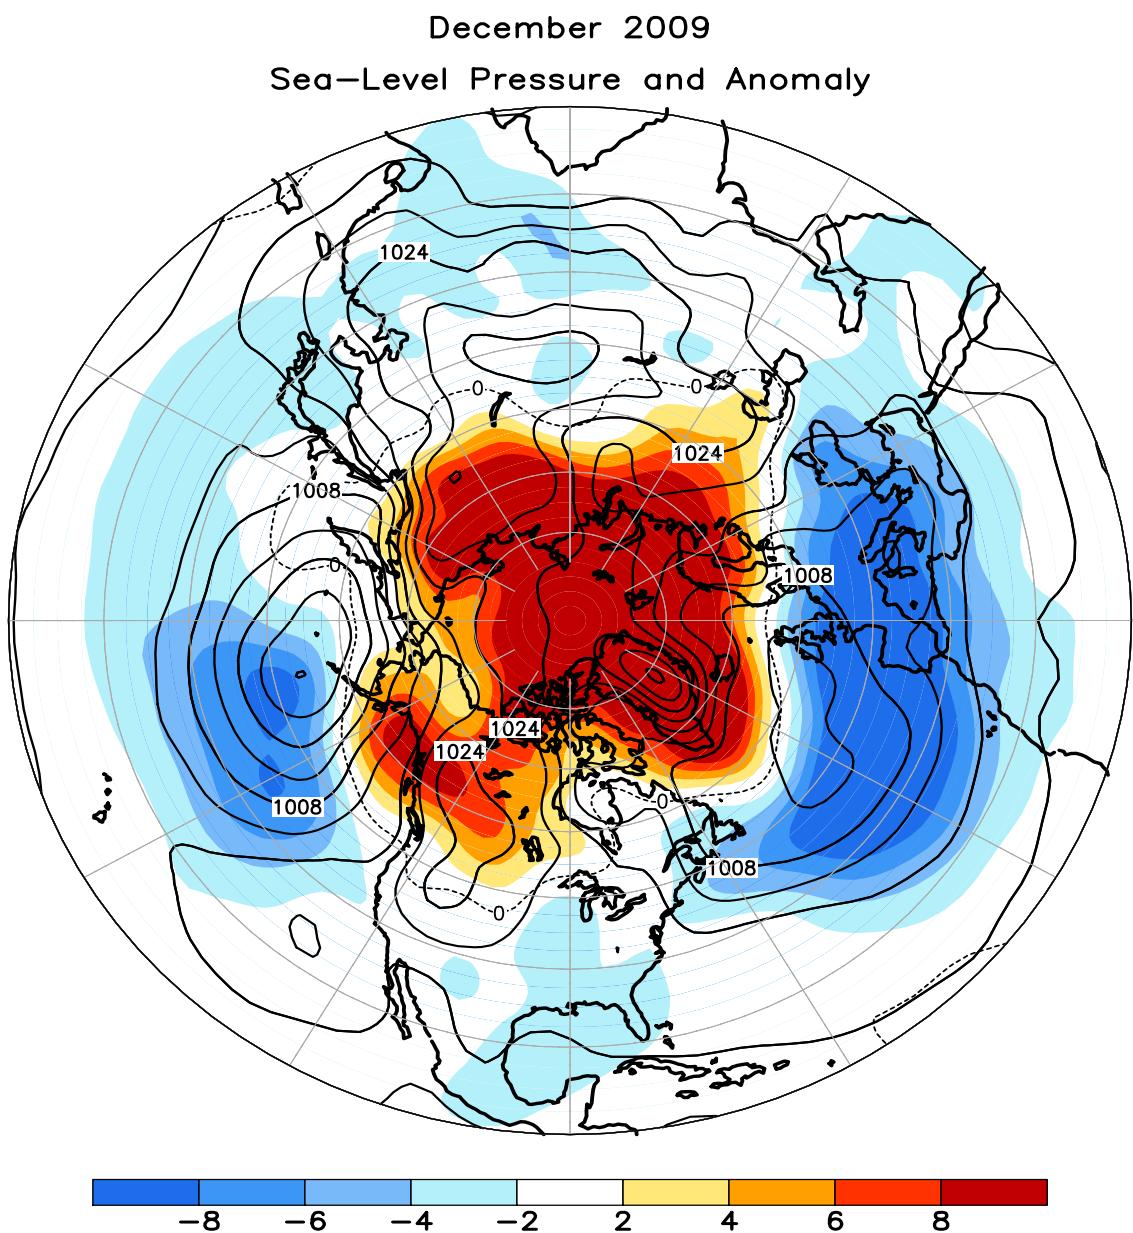

FIGURE E8. Northern Hemisphere mean and anomalous sea level pressure (CDAS/Reanalysis) for DEC 2009. Mean values are denoted by solid contours drawn at an interval of 4 hPa. Anomaly contour interval is 2 hPa with values less (greater) than -2 hPa (2 hPa) indicated by dark (light) shading. Anomalies are calculated as departures from the 1979-95 base period monthly means.

December 2009
500-hPa Height and Anomaly

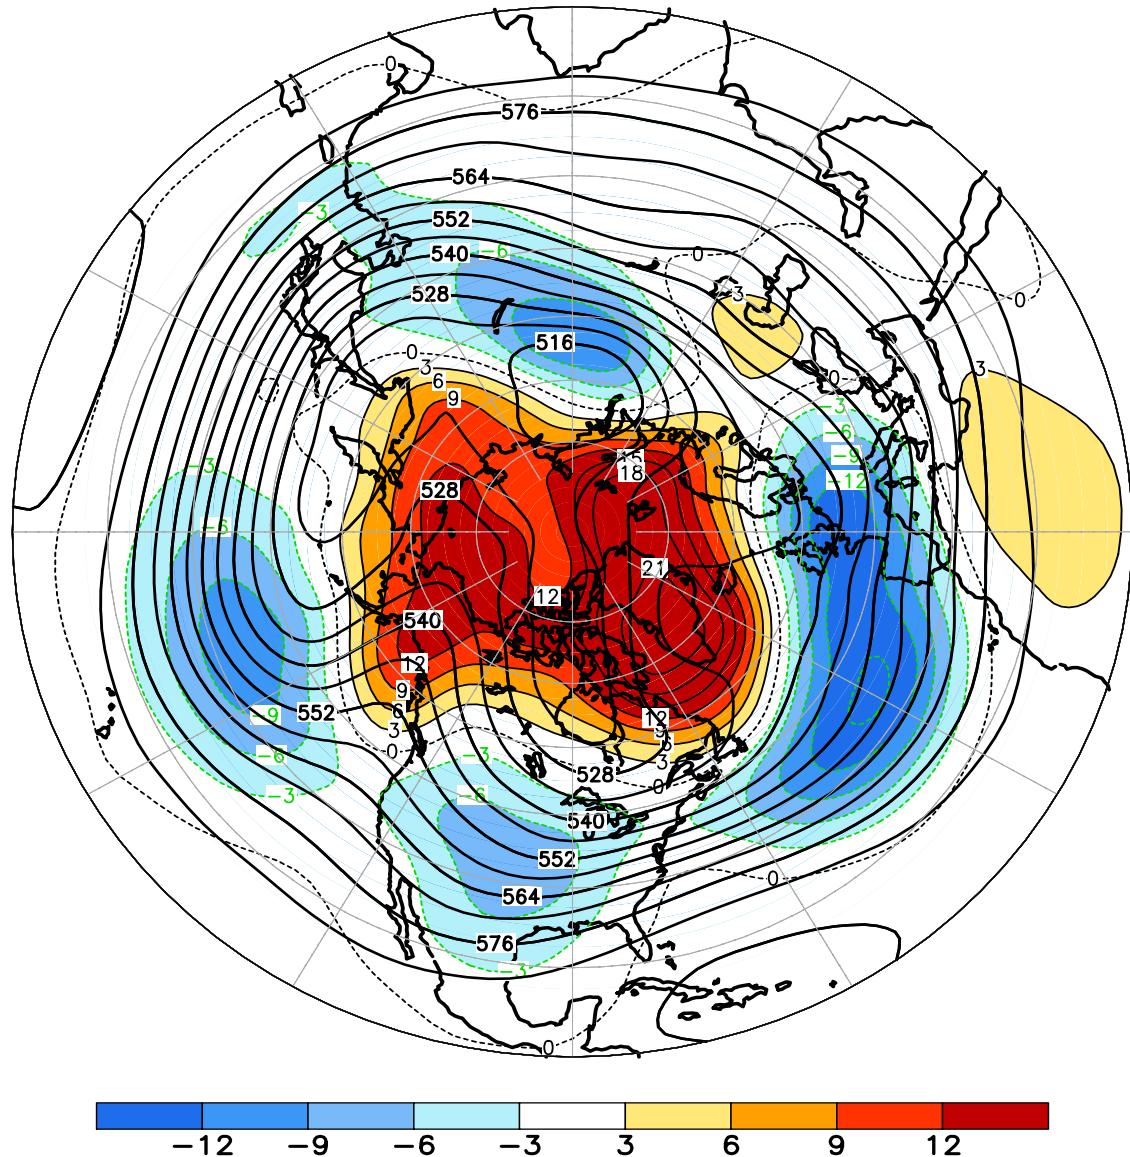

FIGURE E9. Northern Hemisphere mean and anomalous 500-hPa geopotential height (CDAS/Reanalysis) for DEC 2009. Mean heights are denoted by solid contours drawn at an interval of 6 dam. Anomaly contour interval is 3 dam with values less (greater) than -3 dam (3 dam) indicated by dark (light) shading. Anomalies are calculated as departures from the 1979-95 base period monthly means.

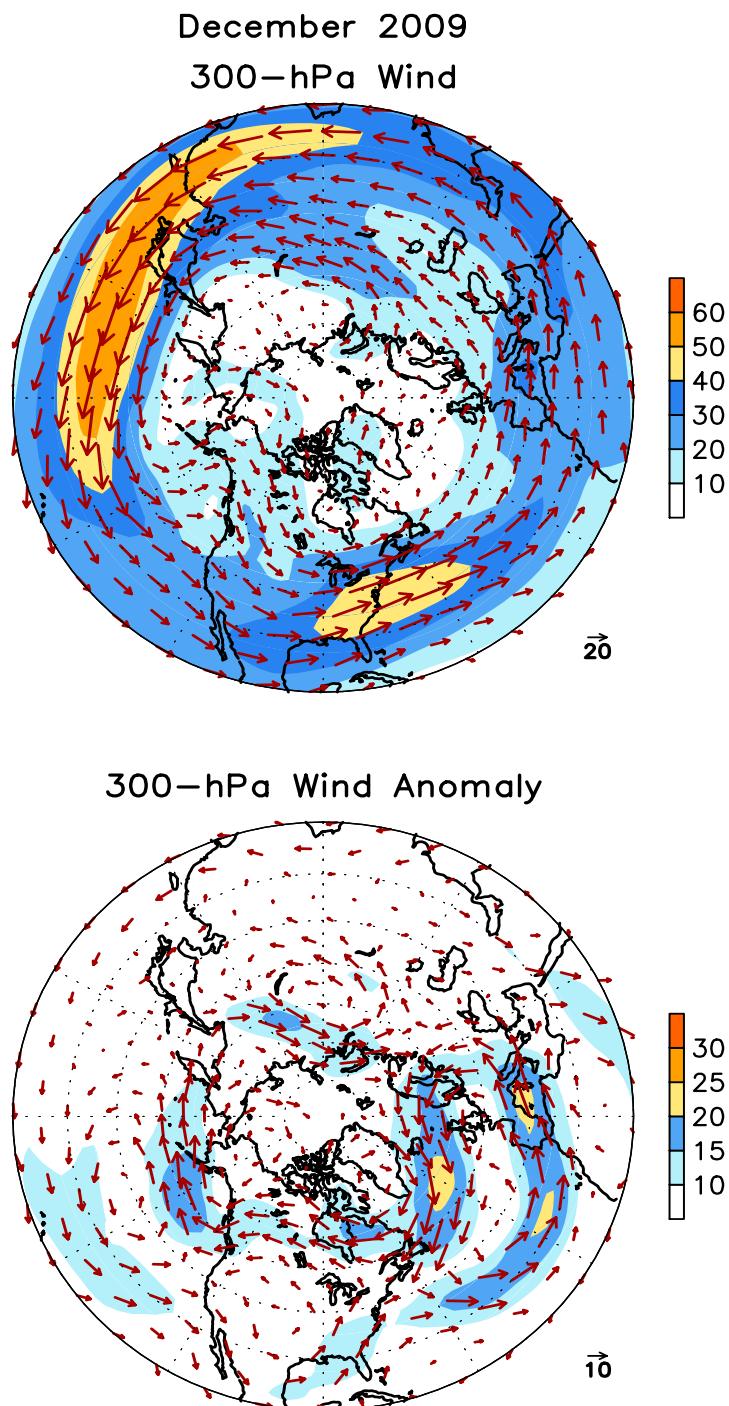

FIGURE E10. Northern Hemisphere mean (left) and anomalous (right) 300-hPa vector wind (CDAS/Reanalysis) for DEC 2009. Mean (anomaly) isotach contour interval is $10\ (5)\ \text{ms}^{-1}$. Values greater than $30\ \text{ms}^{-1}$ (left) and $10\ \text{ms}^{-1}$ (rights) are shaded. Anomalies are departures from the 1979-95 base period monthly means.

December 2009
500-hPa: Percentage of Anomaly Days

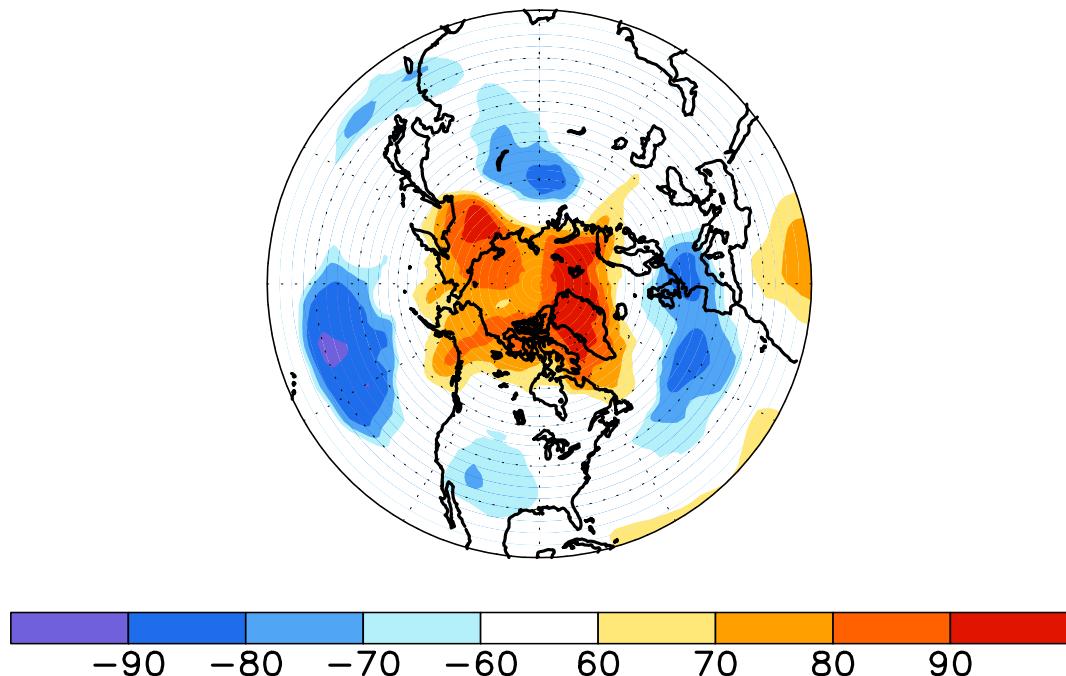

FIGURE E11. Northern Hemisphere percentage of days during DEC 2009 in which 500-hPa height anomalies greater than 15 m (red) and less than -15 m (blue) were observed. Values greater than 70% are shaded and contour interval is 20%.

December 2009
500-hPa Height Anomalies: 40.0N

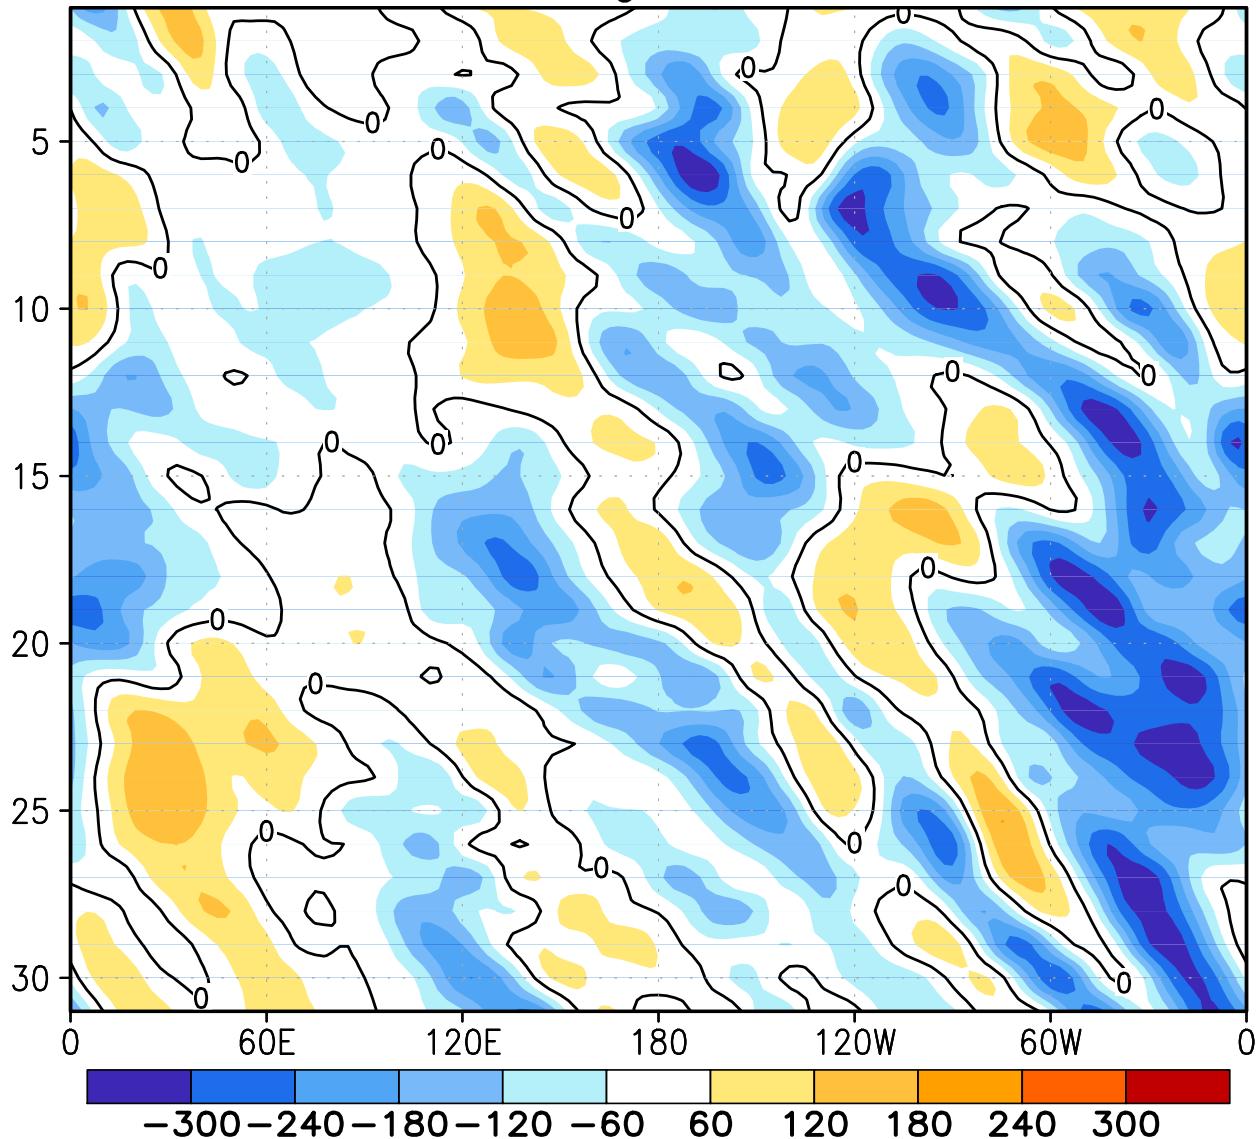

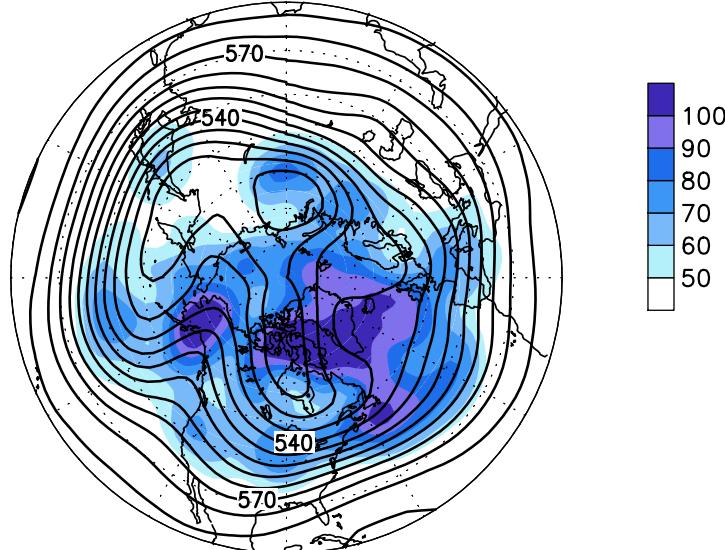

FIGURE E12. Northern Hemisphere: Daily 500-hPa height anomalies for DEC 2009 averaged over the 5° latitude band centered on 40°N. Positive values are indicated by solid contours and dark shading. Negative values are indicated by dashed contours and light shading. Contour interval is 60 m. Anomalies are departures from the 1979-95 base period daily means.

December 2009
 500-hPa Heights (Contours)
 High Frequency Std. Dev. (Shading)

500-hPa Heights (Contours)
 Normalized High Frequency Variance (Shading)

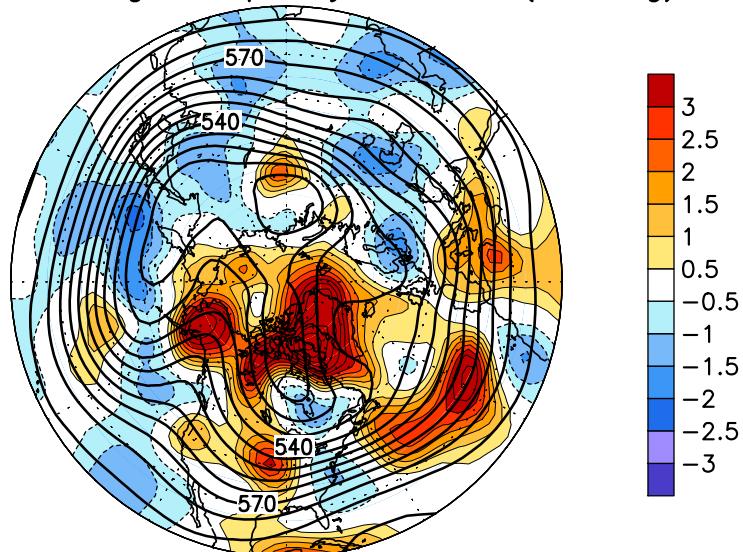

FIGURE E13. Northern Hemisphere 500-hPa heights (thick contours, interval is 6 dam) overlaid with (Top) Standard deviation of 10-day high-pass (HP) filtered height anomalies and (Bottom) Normalized anomalous variance of 10-day HP filtered height anomalies. A Lanczos filter is used to calculate the HP filtered anomalies. Anomalies are departures from the 1979-2000 daily means.

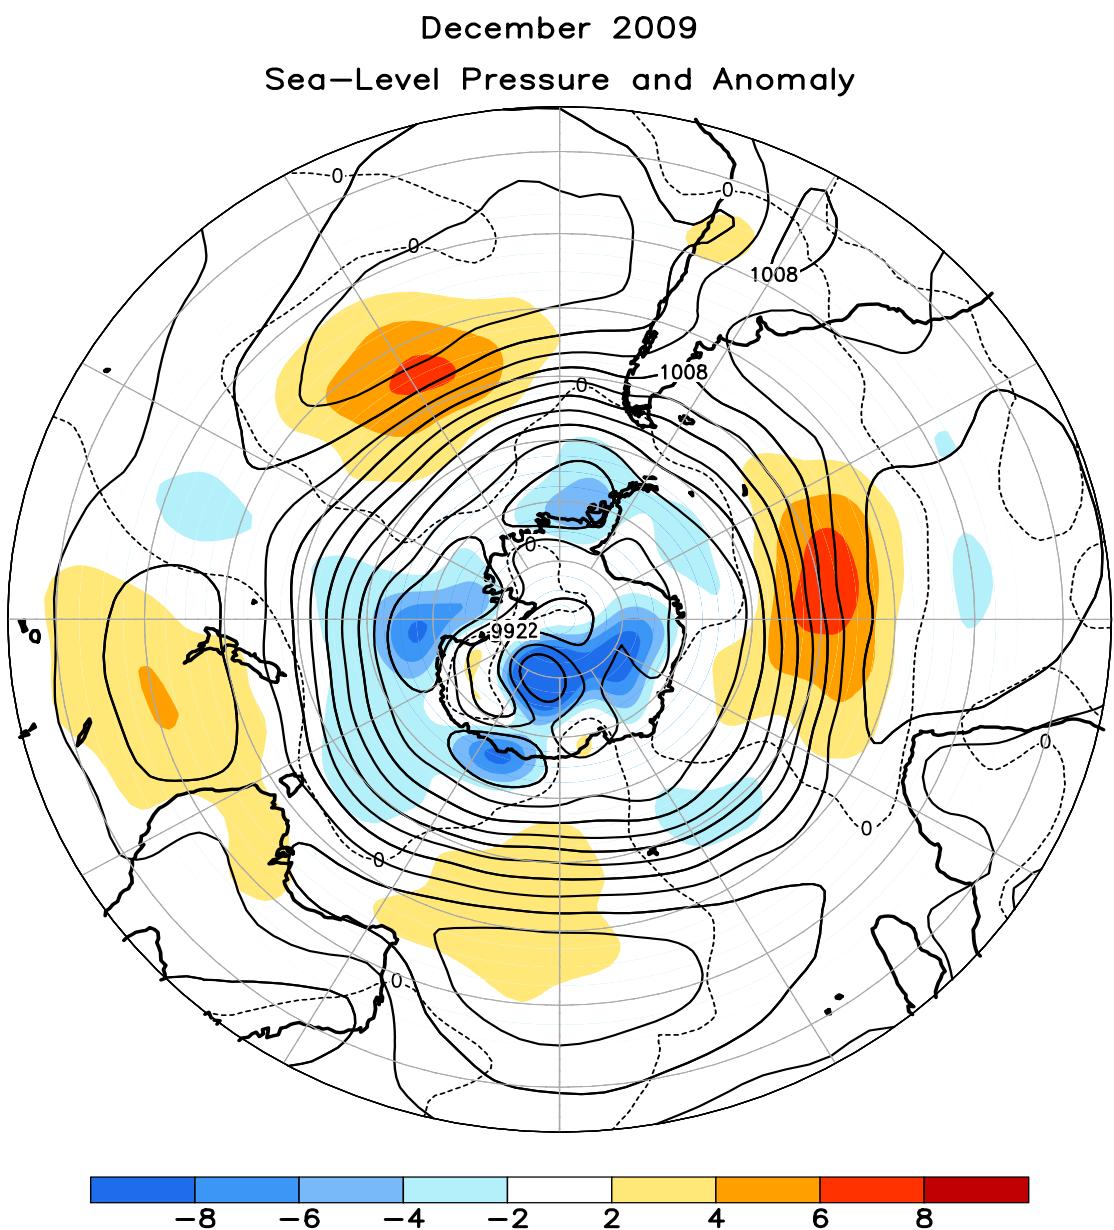

FIGURE E14. Southern Hemisphere mean and anomalous sea level pressure(CDAS/Reanalysis) for DEC 2009. Mean values are denoted by solid contours drawn at an interval of 4 hPa. Anomaly contour interval is 2 hPa with values less (greater) than -2 hPa (2 hPa) indicated by dark (light) shading. Anomalies are calculated as departures from the 1979-95 base period monthly means.

December 2009
500-hPa Height and Anomaly

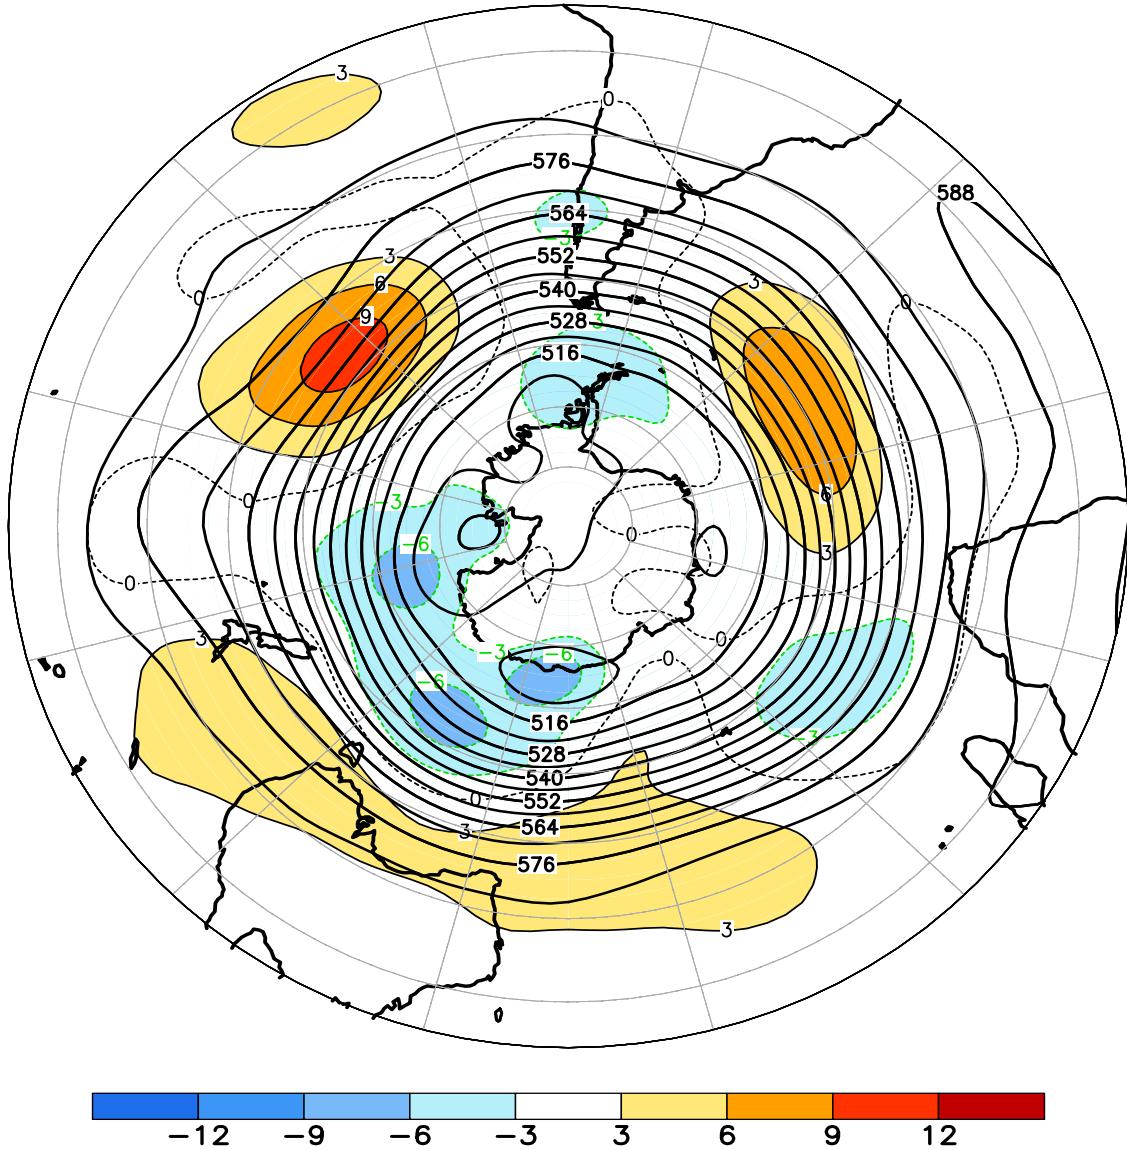

FIGURE E15. Southern Hemisphere mean and anomalous 500-hPa geopotential height (CDAS/Reanalysis) for DEC 2009. Mean heights are denoted by solid contours drawn at an interval of 6 dam. Anomaly contour interval is 3 dam with values less (greater) than -3 dam (3 dam) indicated by dark (light) shading. Anomalies are calculated as departures from the 1979-95 base period monthly means.

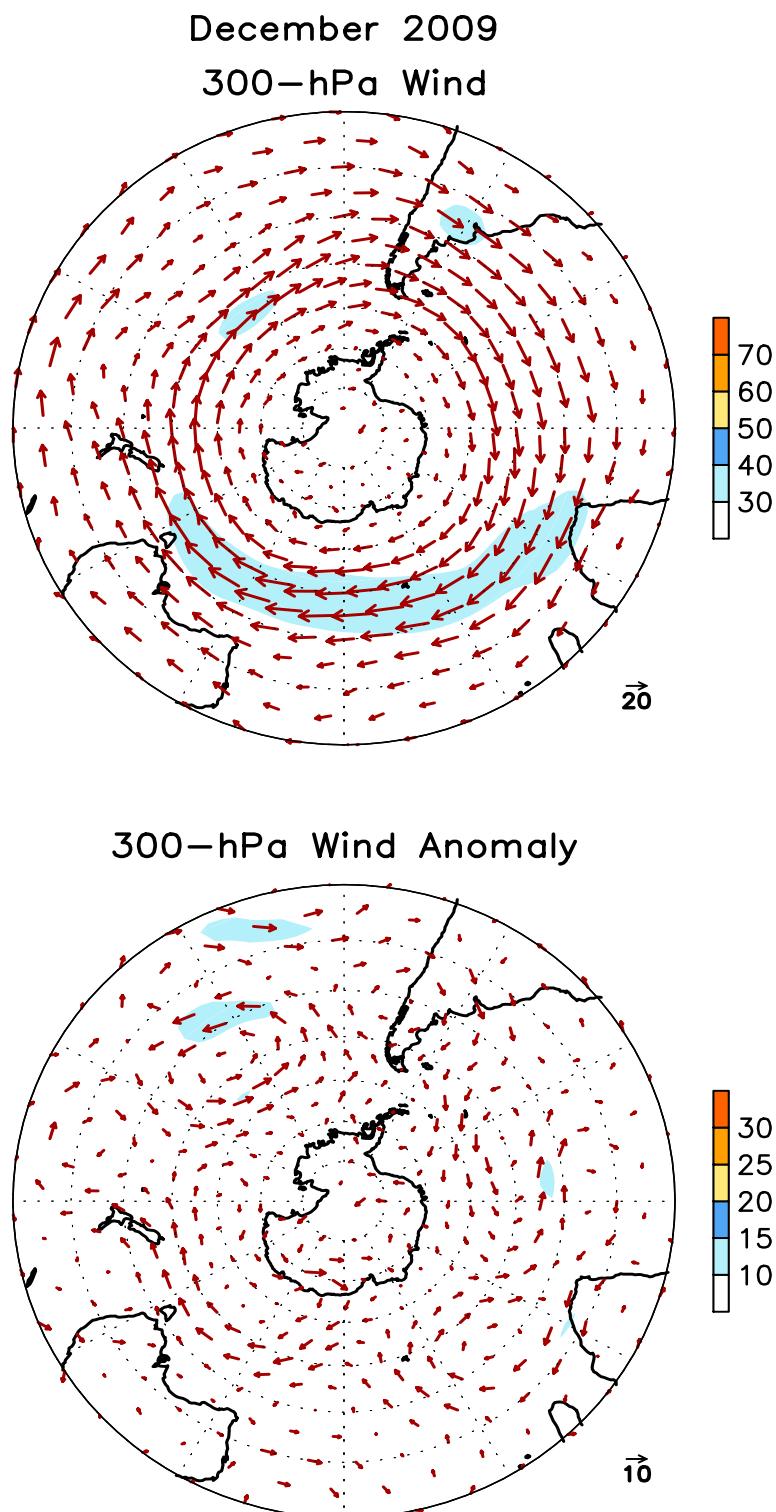

FIGURE E16. Southern Hemisphere mean (left) and anomalous (right) 300-hPa vector wind (CDAS/Reanalysis) for DEC 2009. Mean (anomaly) isotach contour interval is 10 (5) ms^{-1} . Values greater than 30 ms^{-1} (left) and 10 ms^{-1} (rights) are shaded. Anomalies are departures from the 1979-95 base period monthly means.

December 2009
500-hPa: Percentage of Anomaly Days

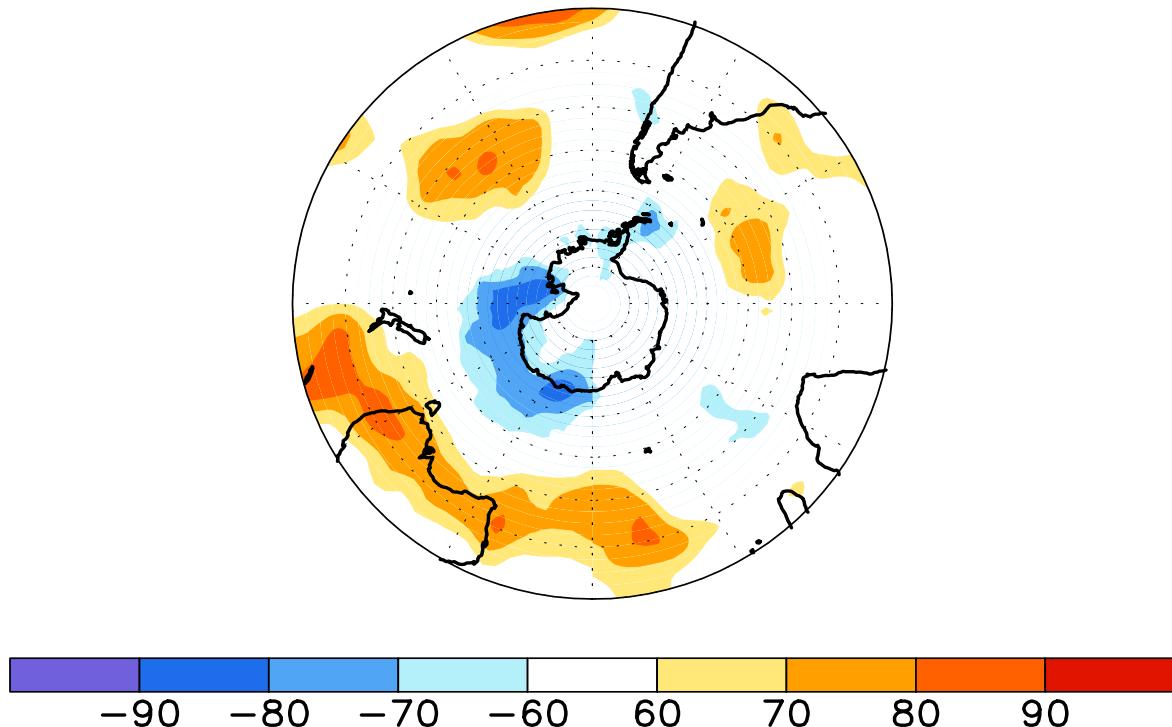

FIGURE E17. Southern Hemisphere percentage of days during DEC 2009 in which 500-hPa height anomalies greater than 15 m (red) and less than -15 m (blue) were observed. Values greater than 70% are shaded and contour interval is 20%.

December 2009
500-hPa Height Anomalies: 40.0S

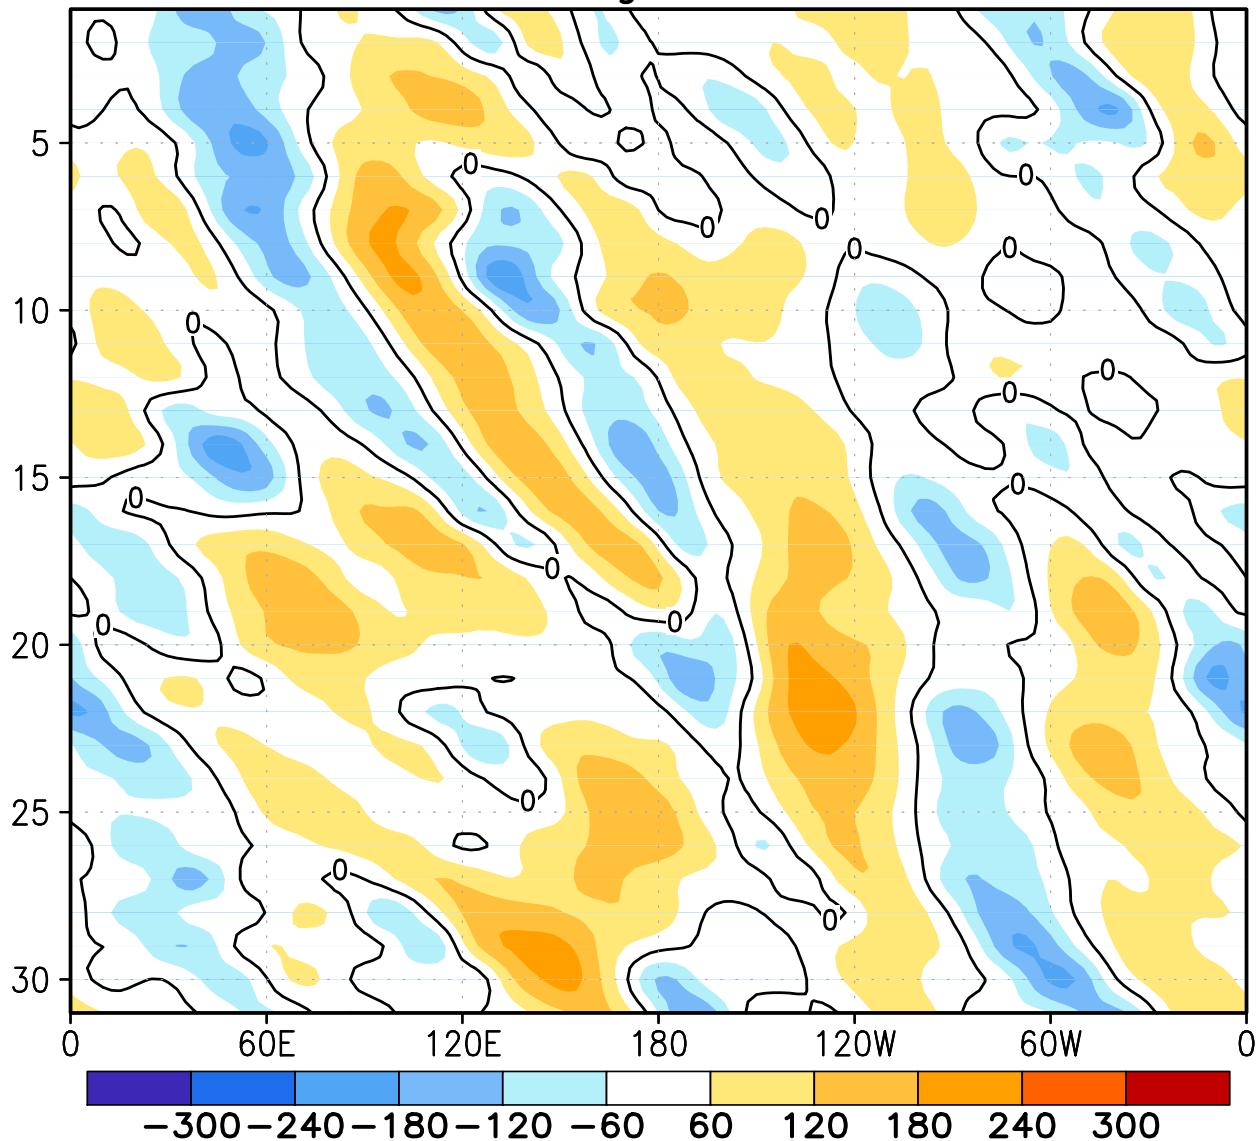

FIGURE E18. Southern Hemisphere: Daily 500-hPa height anomalies for DEC 2009 averaged over the 5° latitude band centered on 40°S. Positive values are indicated by solid contours and dark shading. Negative values are indicated by dashed contours and light shading. Contour interval is 60 m. Anomalies are departures from the 1979-95 base period daily means.

December 2009
Height Anomalies

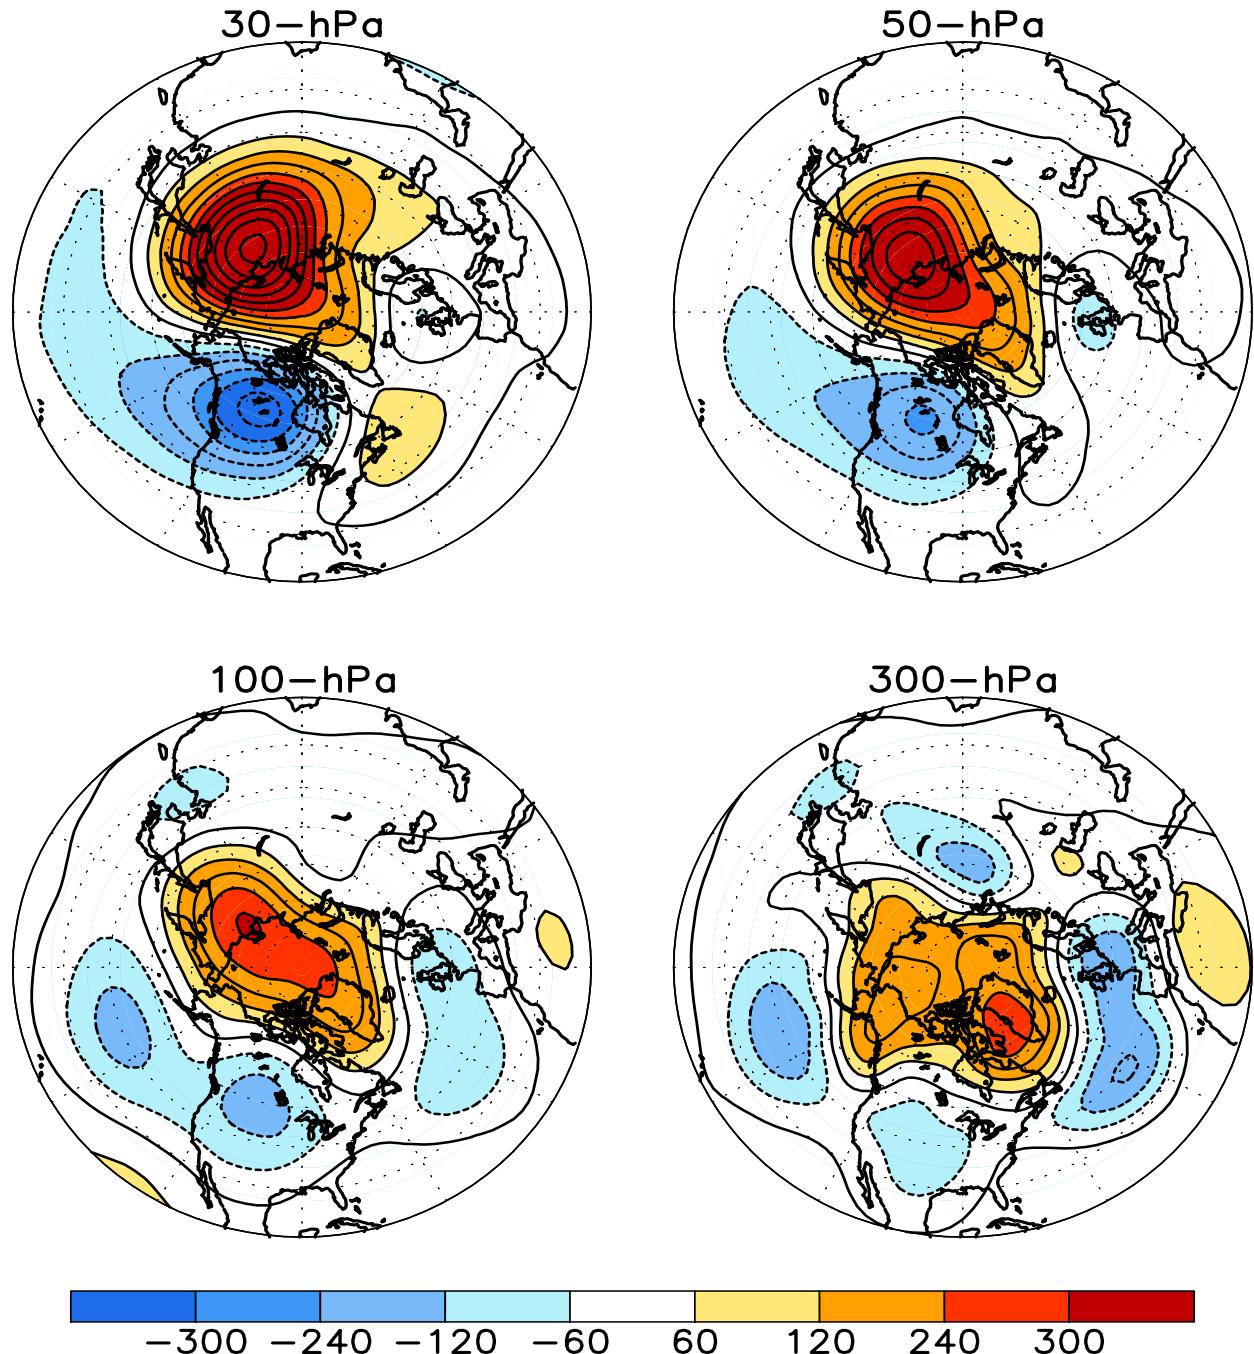

FIGURE S1. Stratospheric height anomalies (m) at selected levels for DEC 2009. Positive values are indicated by solid contours and dark shading. Negative values are indicated by dashed contours and light shading. Contour interval is 60 m. Anomalies are calculated from the 1979–95 base period means. Winter Hemisphere is shown.

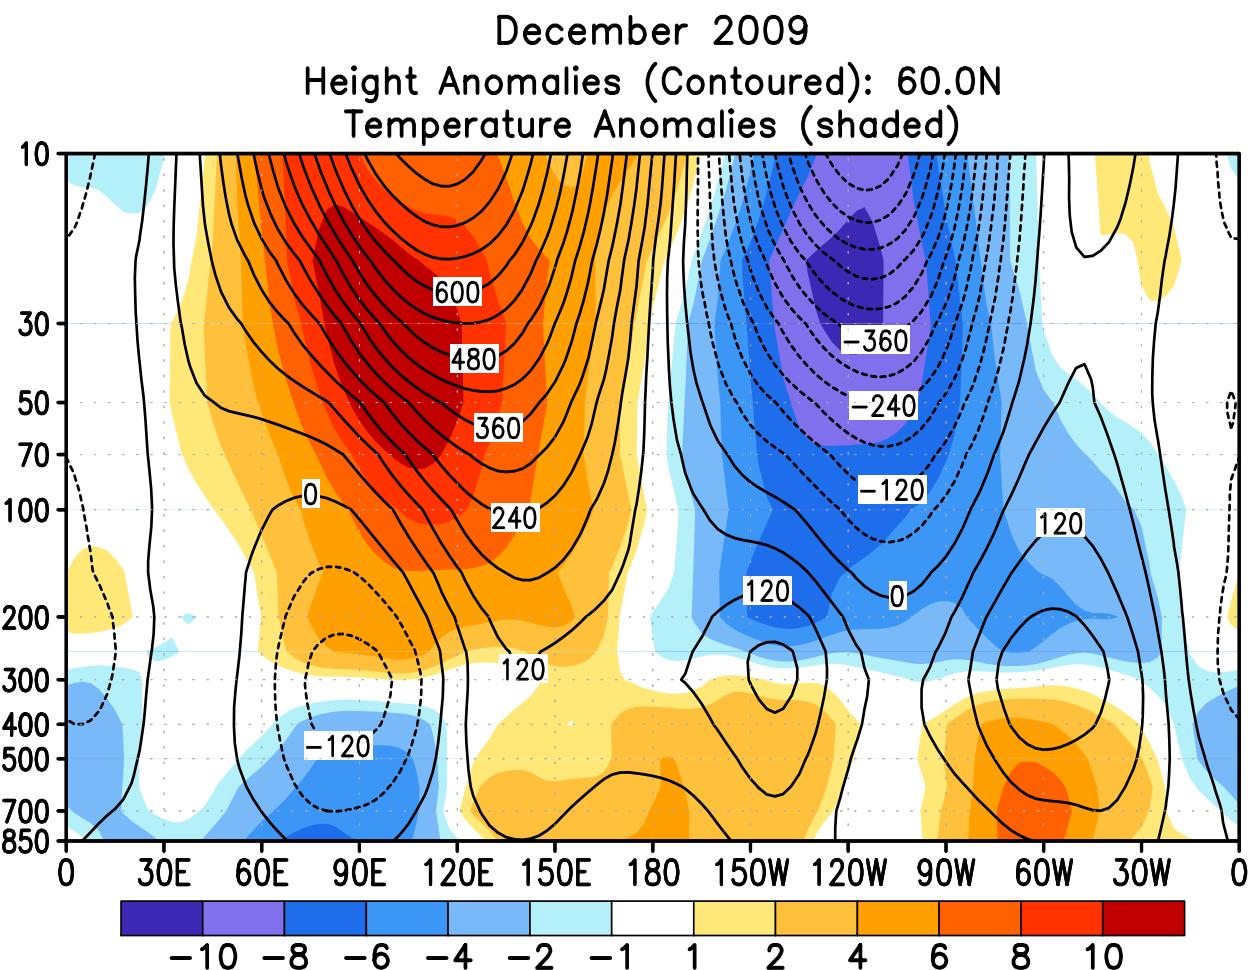

FIGURE S2. Height-longitude sections during DEC 2009 for height anomalies (contour) and temperature anomalies (shaded). In both panels, positive values are indicated by solid contours and dark shading, while negative anomalies are indicated by dashed contours and light shading. Contour interval for height anomalies is 60 m and for temperature anomalies is 2°C. Anomalies are calculated from the 1979–95 base period monthly means. Winter Hemisphere is shown.

50hPa OND Mean Temperature Anomalies

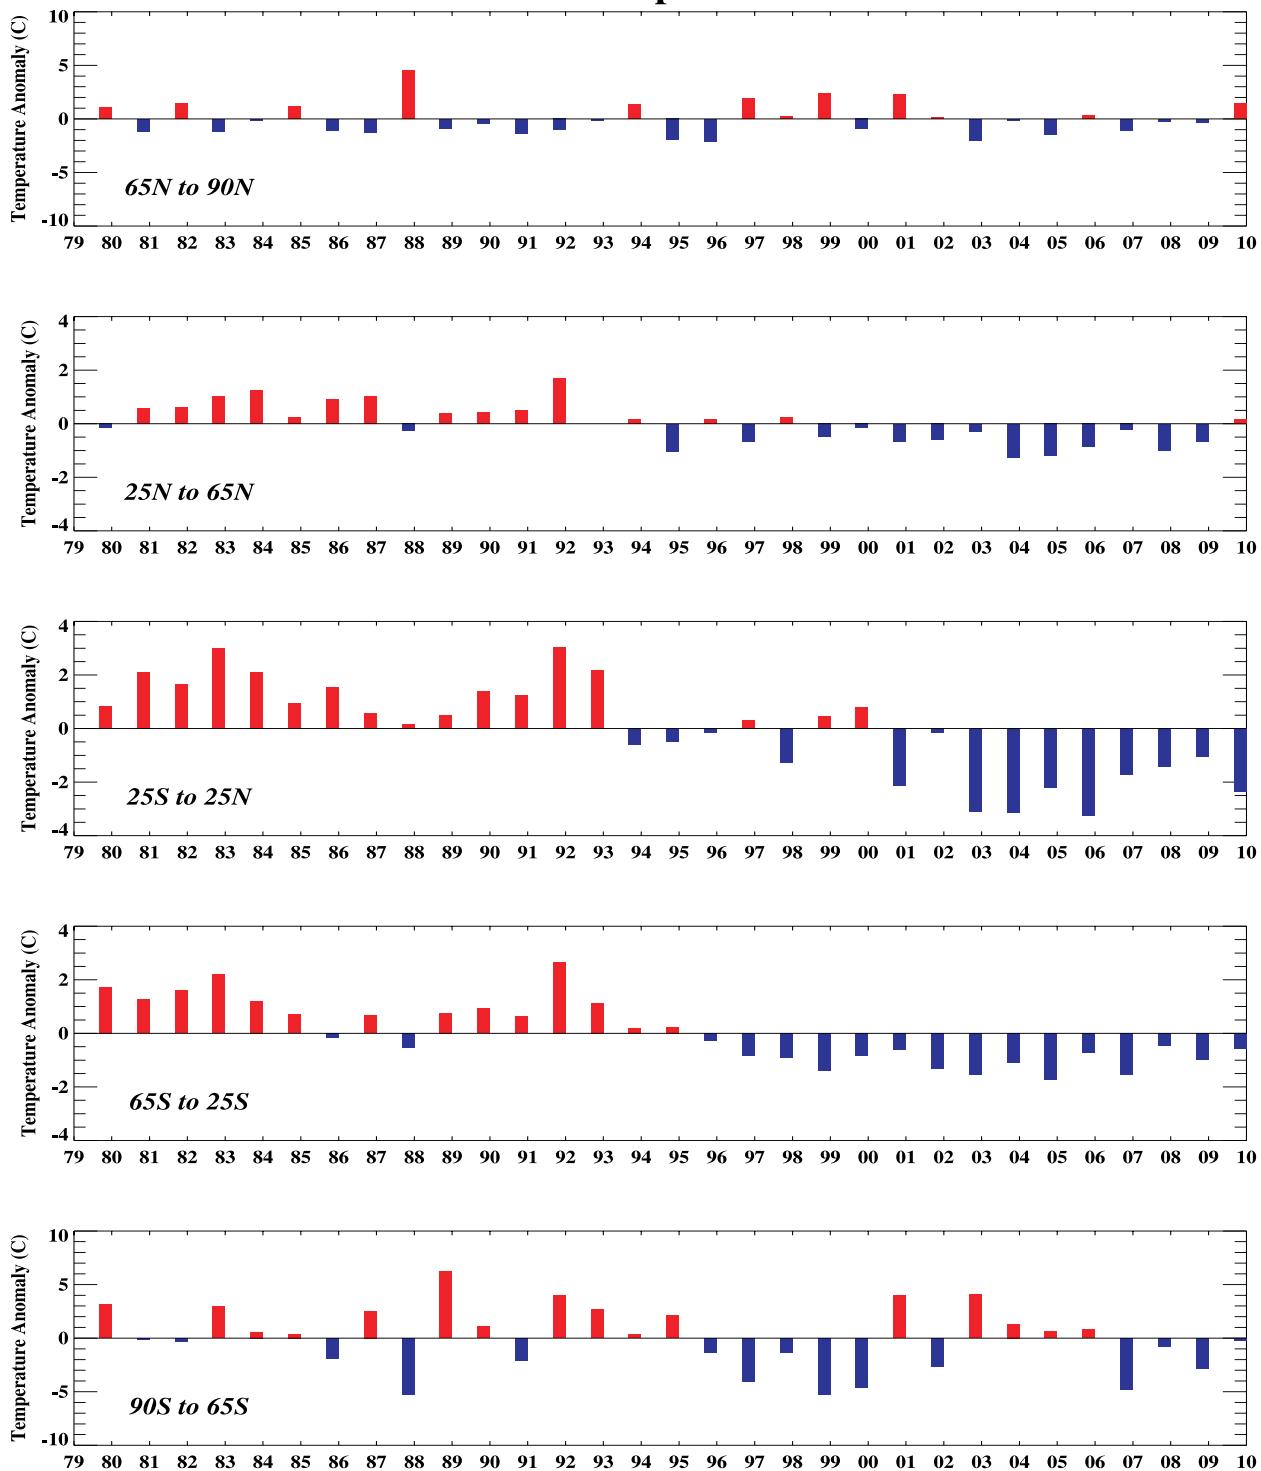

FIGURE S3. Seasonal mean temperature anomalies at 50-hPa for the latitude bands 65° – 90° N, 25° – 65° N, 25° N– 25° S, 25° – 65° S, 65° – 90° S. The seasonal mean is comprised of the most recent three months. Zonal anomalies are taken from the mean of the entire data set.

Zonal Mean Temperature for 2008 & 2009

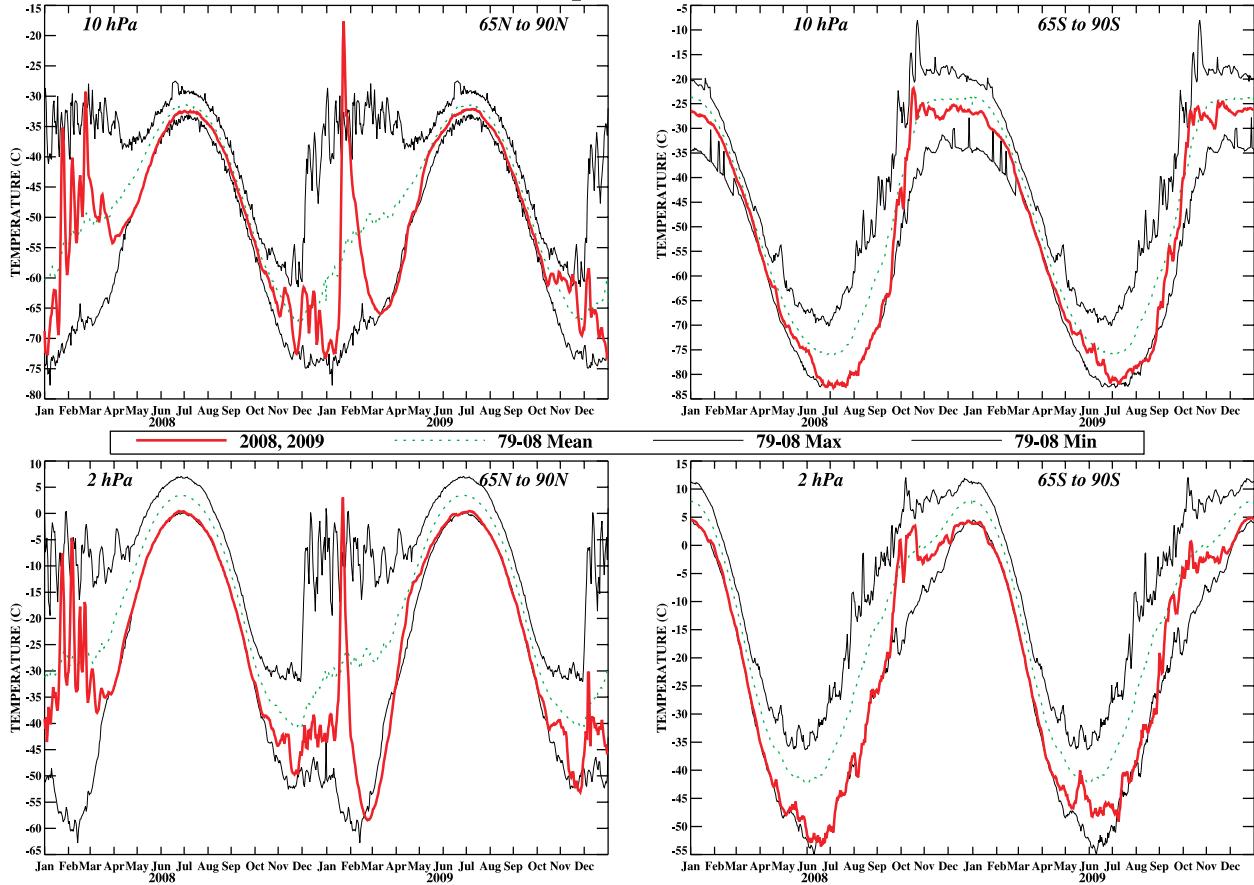

FIGURE S4. Daily mean temperatures at 10-hPa and 2-hPa (thick line) in the region 65° – 90° N and 65° – 90° S for the past two years. Dashed line depicts the 1979–99 base period daily mean. Thin solid lines depict the daily extreme maximum and minimum temperatures.

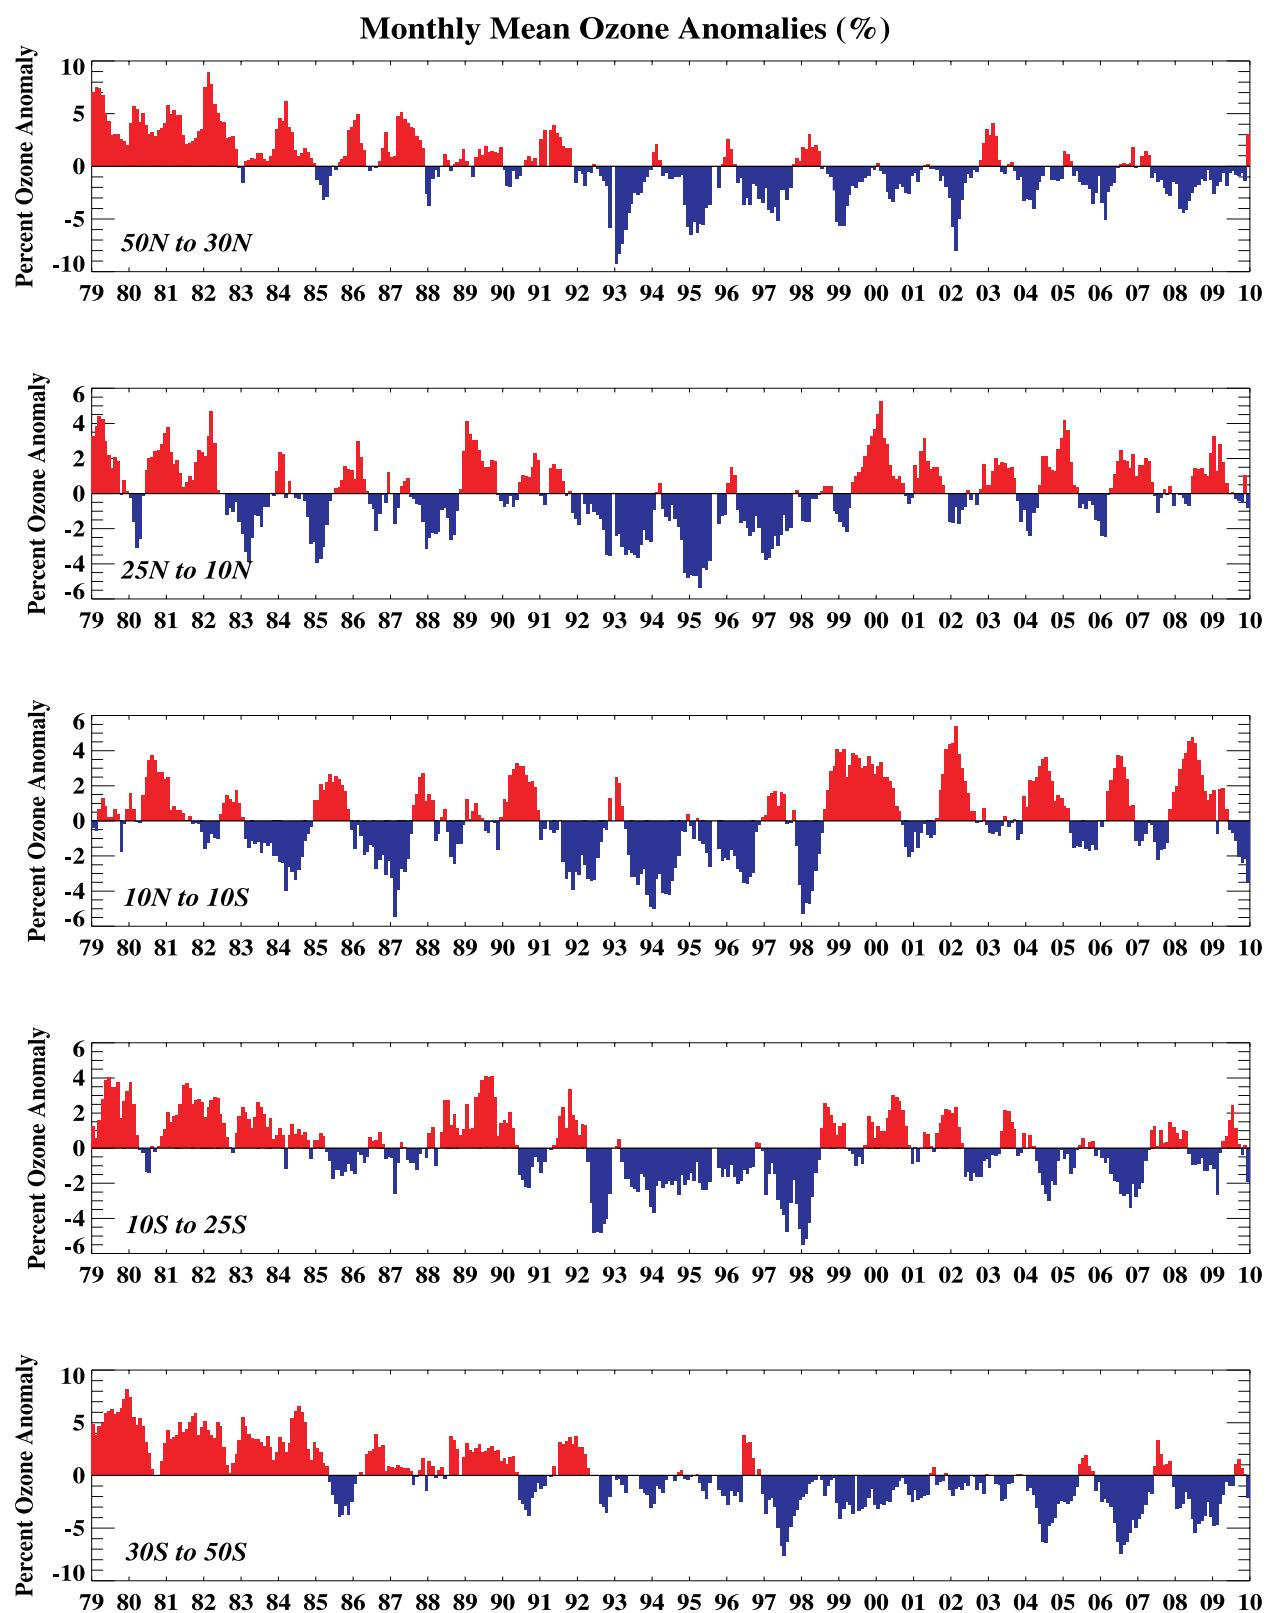

FIGURE S5. Monthly ozone anomalies (percent) from the long term monthly means for five zones: 50N-30N (NH mid-latitudes), 25N-10N (NH tropical surf zone), 10N-10S (Equatorial-QBO zone), 10S-25S (SH tropical surf zone), and 30S-50S (SH mid-latitudes). The long term monthly means are determined from the entire data set beginning in 1979.

DECEMBER PERCENT DIFF (2009 - AVG(79-86))

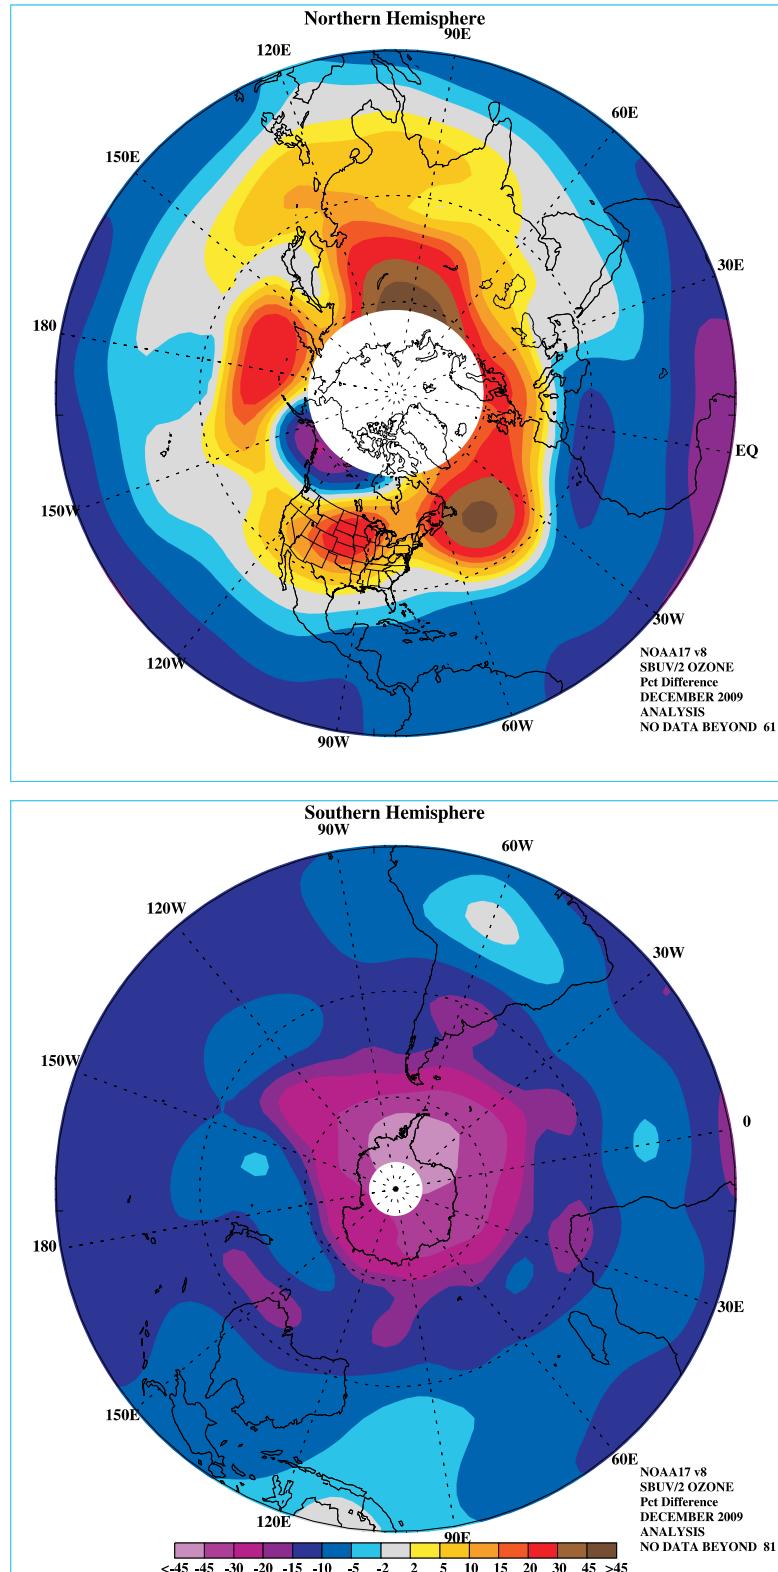

FIGURE S6. Northern (top) and Southern (bottom) Hemisphere total ozone anomaly (percent difference from monthly mean for the period 1979–86). The region near the winter pole has no SBUV/2 data.

Fz at 100 hPa (Dec. 2009)

30N–90N

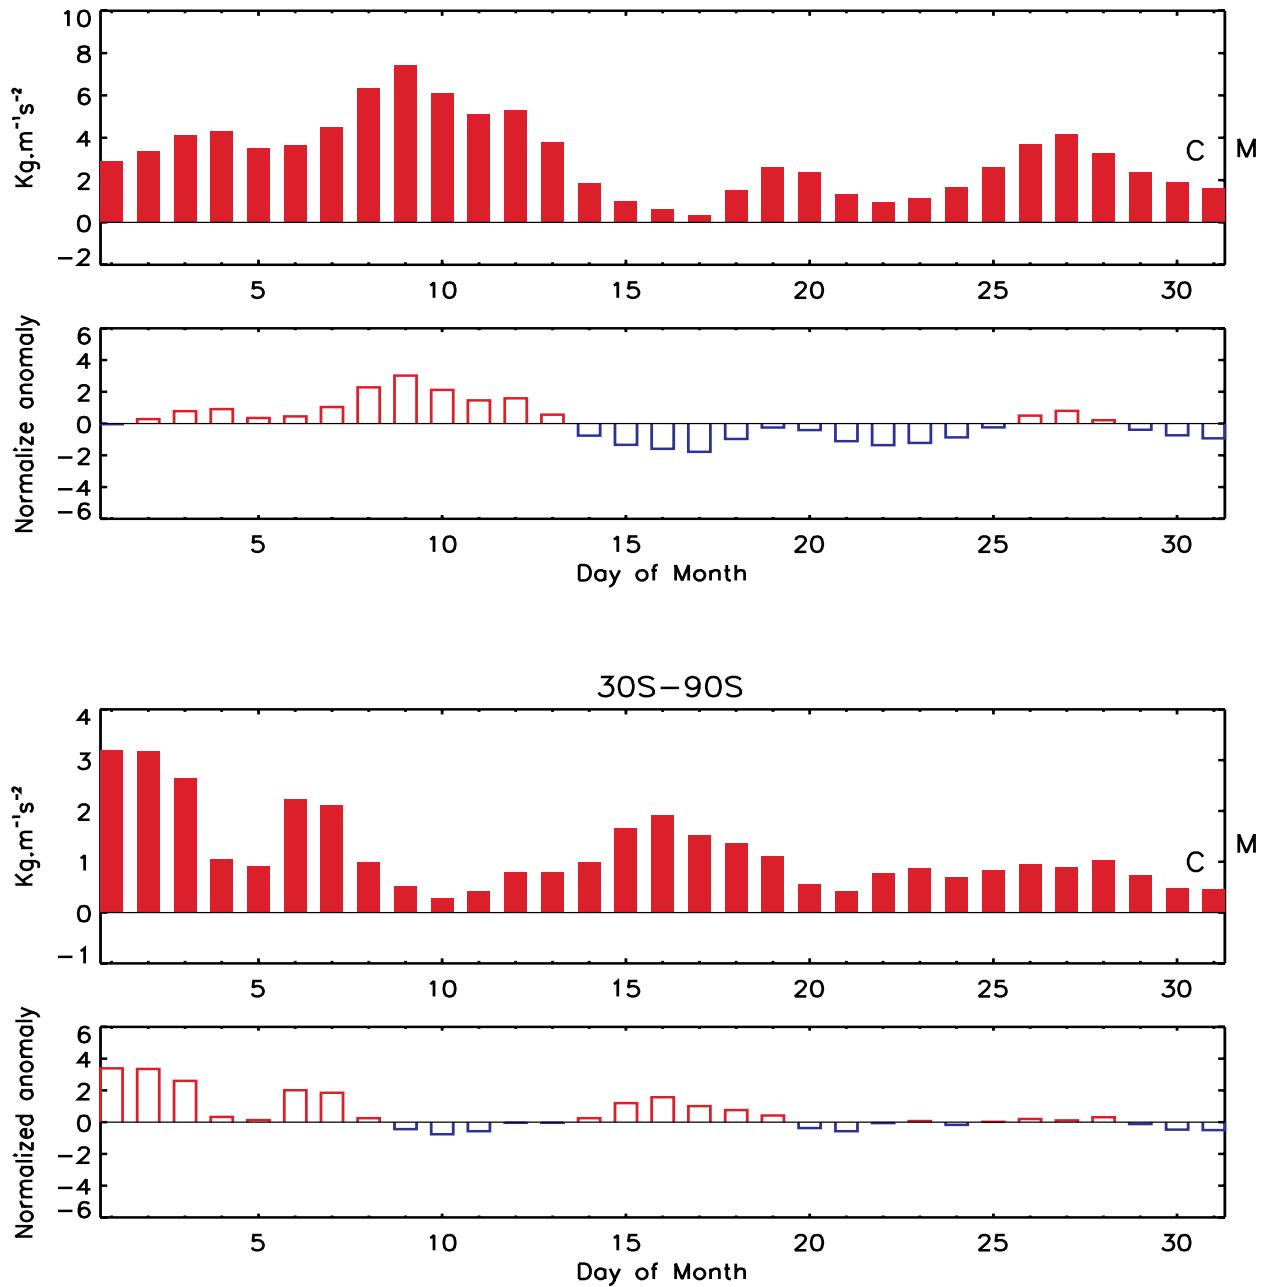

FIGURE S7. Daily vertical component of EP flux (which is proportional to the poleward transport of heat or upward transport of potential energy by planetary wave) at 100 hPa averaged over (top) 30°N–90°N and (bottom) 30°S–90°S for DEC 2009. The EP flux unit ($\text{kg m}^{-1} \text{s}^{-2}$) has been scaled by multiplying a factor of the Brunt Vaisala frequency divided by the Coriolis parameter and the radius of the earth. The letter 'M' indicates the current monthly mean value and the letter 'C' indicates the climatological mean value. Additionally, the normalized departures from the monthly climatological EP flux values are shown.

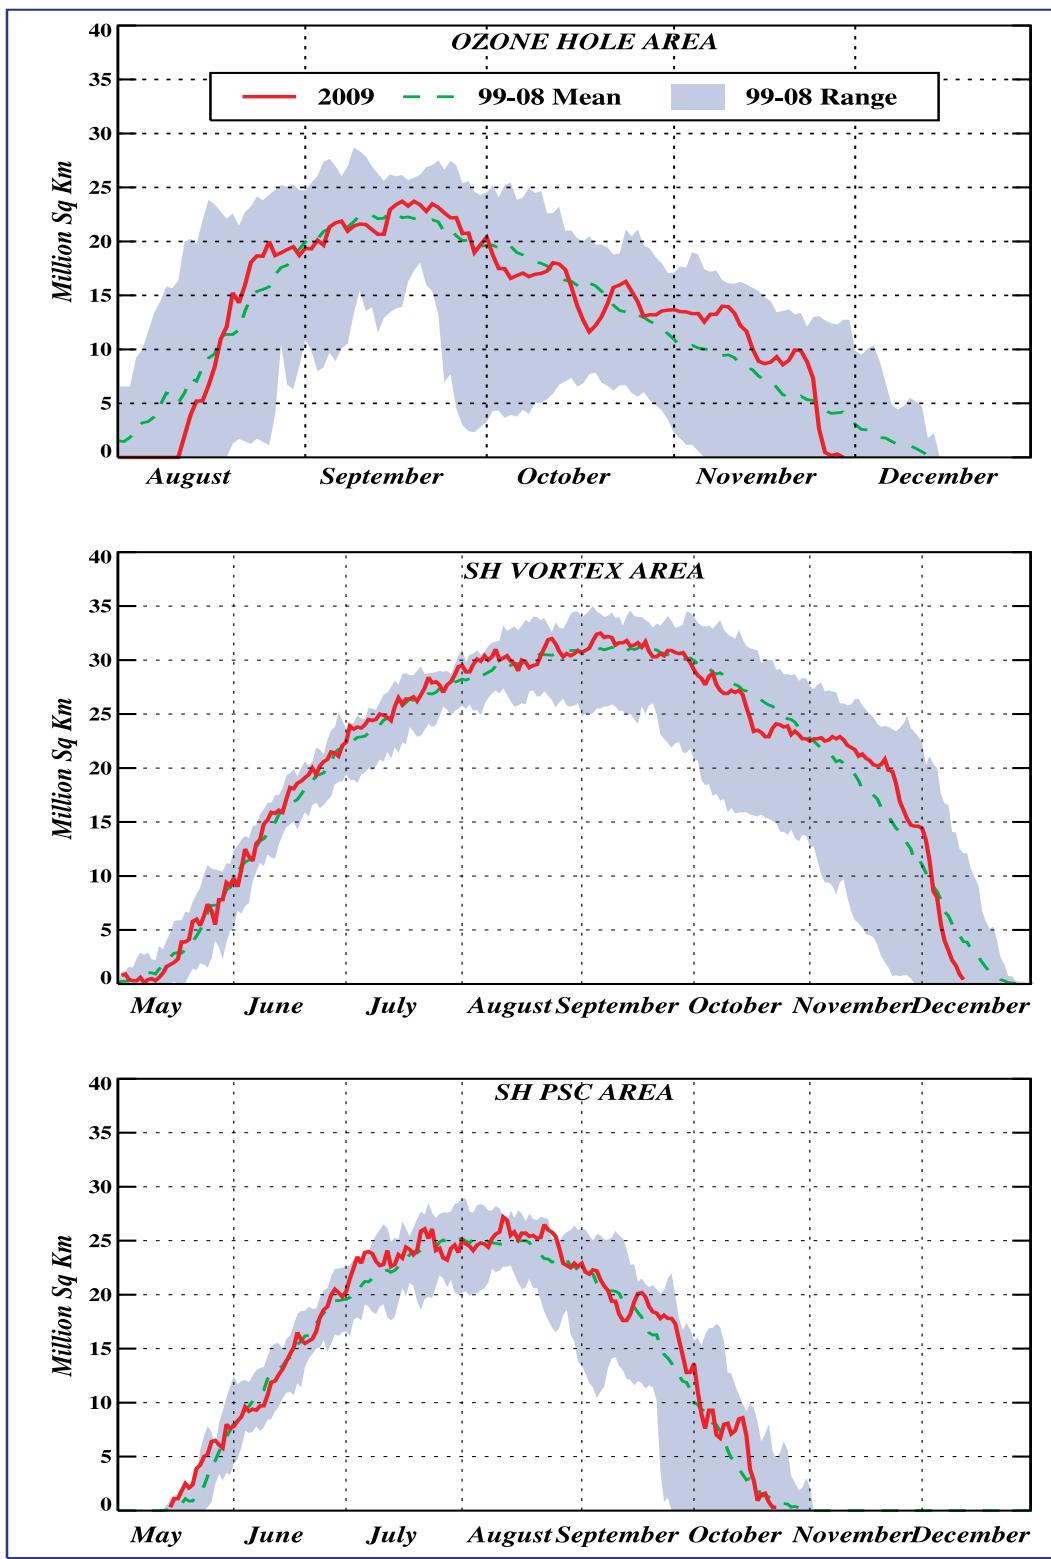

FIGURE S8. Daily time series showing the size of the SH polar vortex (representing the area enclosed by the 32 PVU contour on the 450K isentropic surface), and the areal coverage of temperatures $< -78^{\circ}\text{C}$ on the 450K isentropic surface.

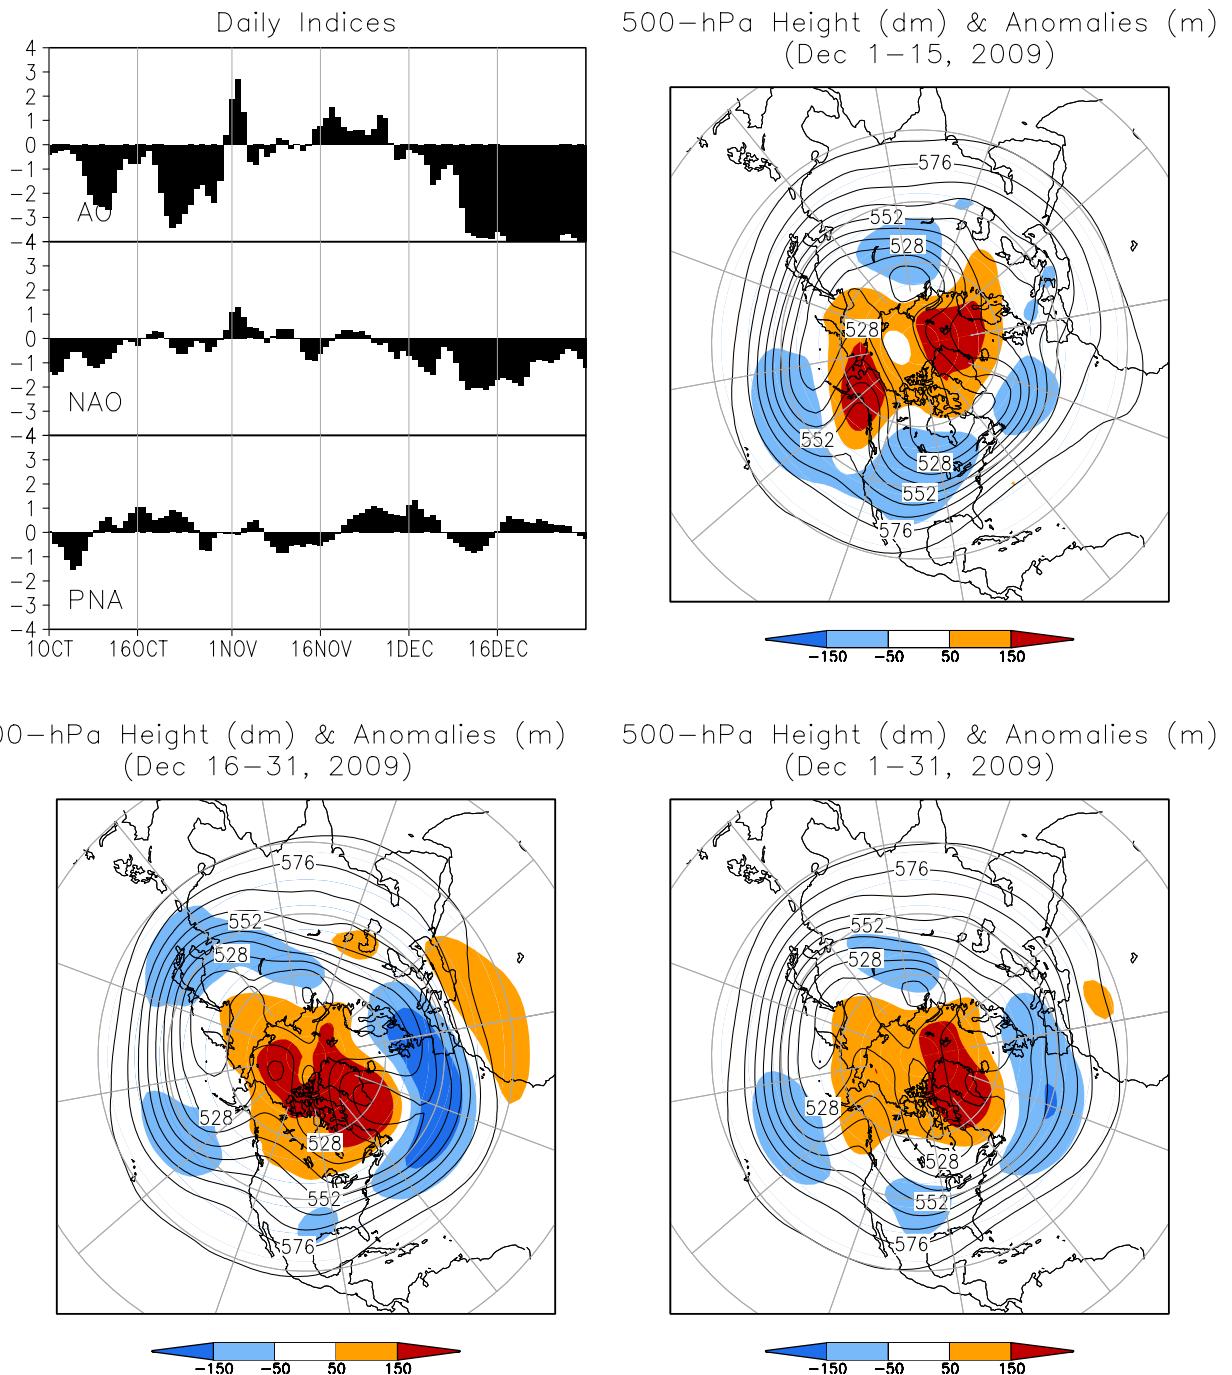

FIGURE A2.1. (a) Daily amplitudes of the Arctic Oscillation (AO), the North Atlantic Oscillation (NAO), and the Pacific-North American (PNA) pattern. The pattern amplitudes for the AO, (NAO, PNA) are calculated by projecting the daily 1000-hPa (500-hPa) height anomaly field onto the leading EOF obtained from standardized time-series of daily 1000-hPa (500-hPa) height for all months of the year. The base period is 1979–2000.

(b-d) Northern Hemisphere mean and anomalous 500-hPa geopotential height (CDAS/Reanalysis) for selected periods during DEC 2009 are shown in the remaining 3 panels. Mean heights are denoted by solid contours drawn at an interval of 8 dam. Dark (light) shading corresponds to anomalies greater than 50 m (less than -50 m). Anomalies are calculated as departures from the 1979–95 base period daily means.

**SSMI/S Snow Cover for Dec 2009
anomaly based on departure from SSM/I 1987–2006 baseline**

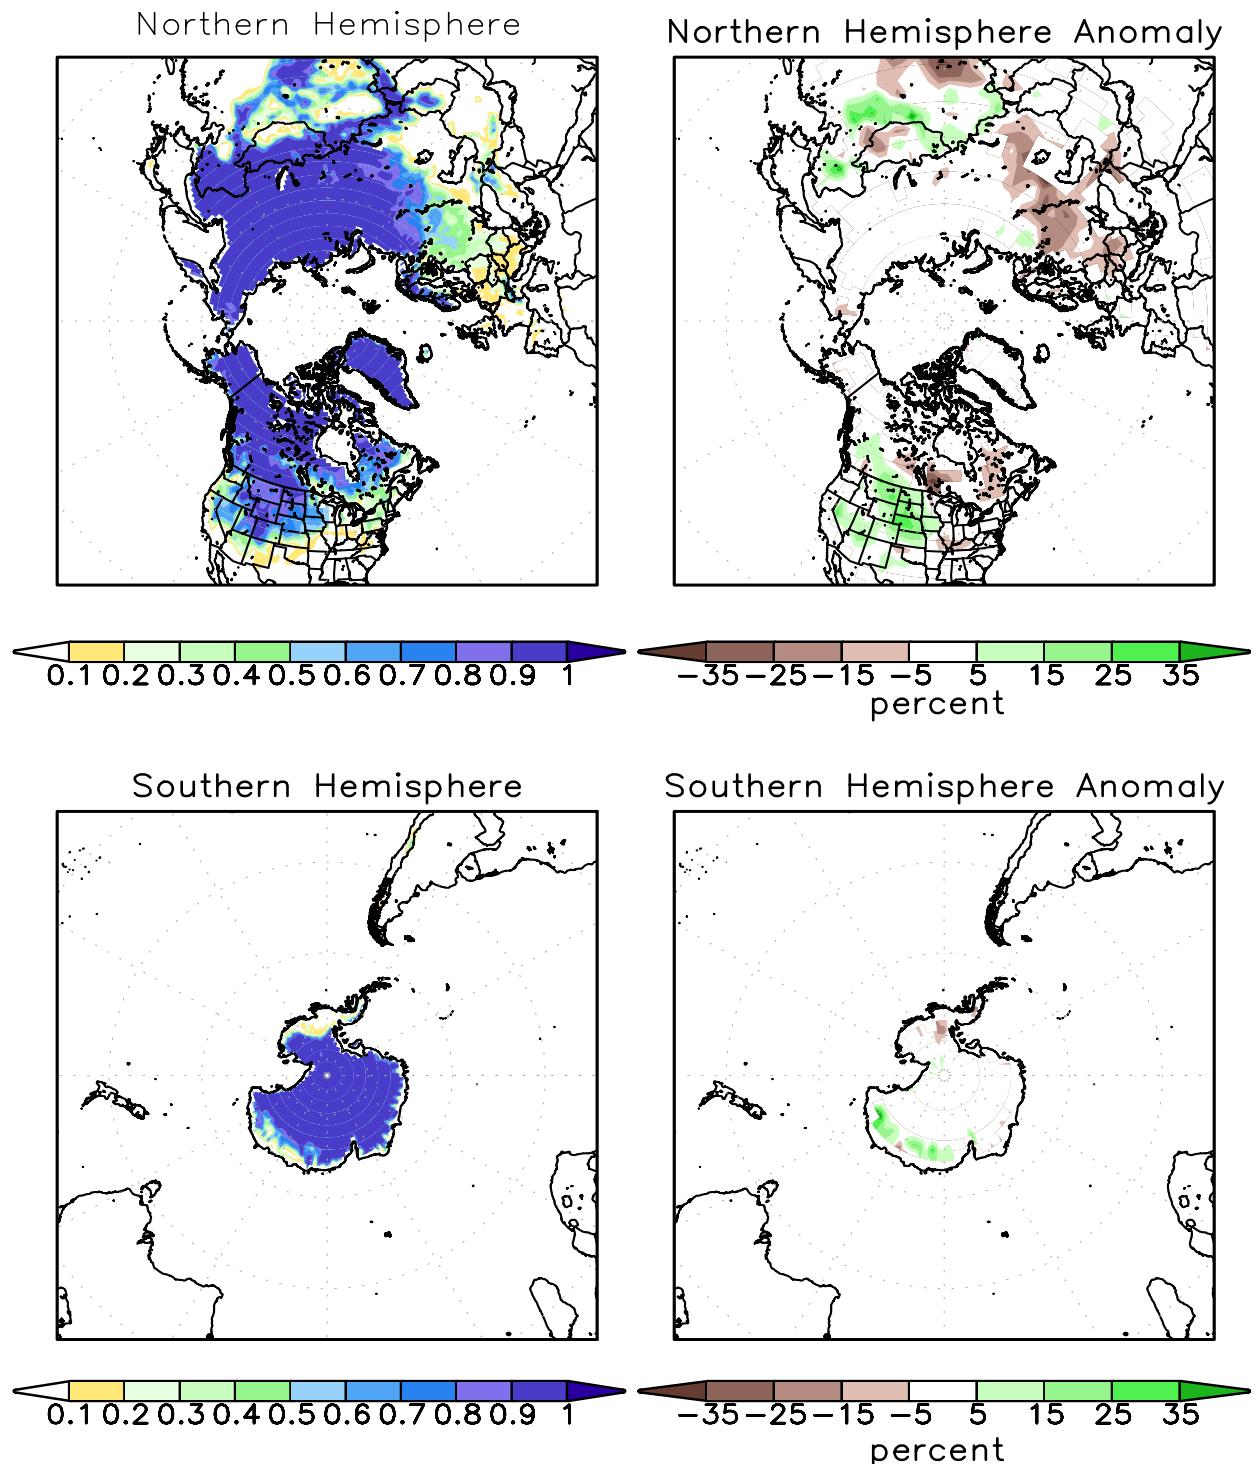

FIGURE A2.2. SSM/I derived snow cover frequency (%) (left) and snow cover anomaly (%) (right) for the month of DEC 2009 based on 1987 - 2006 base period for the Northern Hemisphere (top) and Southern Hemisphere (bottom). It is generated using the algorithm described by Ferraro et. al, 1996, Bull. Amer. Meteor. Soc., vol 77, 891-905.
