Climate Prediction Center / NCEP
13 May 2024
Outline

Summary
Recent Evolution and Current Conditions
Oceanic Niño Index (ONI)
Pacific SST Outlook
U.S. Seasonal Precipitation and Temperature Outlooks
Summary
ENSO Alert System Status: El Niño Advisory / La Niña Watch

El Niño is transitioning toward ENSO-neutral.*

Equatorial sea surface temperatures (SSTs) are above average in the western and central Pacific Ocean, and below-average SSTs are emerging in parts of the eastern Pacific Ocean.

A transition from El Niño to ENSO-neutral is likely in the next month. La Niña may develop in June-August 2024 (49% chance) or July-September (69% chance).*

* Note: These statements are updated once a month (2nd Thursday of each month) in association with the ENSO Diagnostics Discussion, which can be found by clicking here.
From March-October 2023, positive sea surface temperature (SST) anomalies in the eastern Pacific Ocean expanded and shifted westward.

In October and November 2023, SST anomalies increased in the central and east-central Pacific.

Since late December 2023, positive SST anomalies have weakened across most of the Pacific.

Since mid March 2024, below-average SSTs have emerged in small regions of the eastern Pacific.
Niño Region SST Departures (°C) Recent Evolution

The latest weekly SST departures are:

- Niño 4: 0.8°C
- Niño 3.4: 0.3°C
- Niño 3: 0.0°C
- Niño 1+2: -0.4°C
SST Departures (°C) in the Tropical Pacific During the Last Four Weeks

In the last four weeks, equatorial SSTs were above average the central and western Pacific Ocean. Near-to-below-average SSTs were evident in parts of the east-central and eastern Pacific Ocean.
During the last four weeks, equatorial SSTs were above average across the western and central Pacific Ocean, the Indian Ocean, and the Atlantic Ocean. Near-to-below-average SSTs were evident in parts of the eastern Pacific Ocean.
During the last 4 weeks, above-average SSTs have gradually weakened across the equatorial Pacific Ocean.

Below-average SSTs have persisted in parts of the east-central and eastern Pacific Ocean.
During the last four weeks, negative SST anomaly changes were observed in the east-central and eastern equatorial Pacific Ocean.
Upper-Ocean Conditions in the Equatorial Pacific

The basin-wide equatorial upper ocean (0-300 m) heat content is greatest prior to and during the early stages of a Pacific warm (El Niño) episode (compare top 2 panels), and least prior to and during the early stages of a cold (La Niña) episode.

The slope of the oceanic thermocline is least (greatest) during warm (cold) episodes.

Recent values of the upper-ocean heat anomalies (below average) and thermocline slope index (slightly above average) reflect a weakening El Niño.

The *monthly thermocline slope index* represents the difference in anomalous depth of the 20°C isotherm between the western Pacific (160°E-150°W) and the eastern Pacific (90°-140°W).
Positive subsurface temperature anomalies persisted through mid-January 2024. Variability in the positive anomalies was associated with several oceanic Kelvin waves. Starting in November 2023, positive subsurface temperature anomalies weakened to near zero. From late January to mid-April 2024, negative temperature anomalies emerged and strengthened. Since mid-April, negative anomalies have weakened slightly.
Over the last couple months, negative subsurface temperature anomalies have dominated the equatorial Pacific Ocean.

Below-average temperatures reached the surface in the eastern Pacific Ocean (near 130°-90°W).
OLR anomalies were weak across most of the equatorial Pacific. Above-average OLR (suppressed convection and precipitation) persisted around the Philippines and Southeast Asia.

Low-level (850-hPa) winds were near average over most of the tropical Pacific Ocean.

Upper-level (200-hPa) wind anomalies were cross equatorial near the Date Line and east-central equatorial Pacific.
Intraseasonal variability in the atmosphere (wind and pressure), which is often related to the Madden-Julian Oscillation (MJO), can significantly impact surface and subsurface conditions across the Pacific Ocean.

Related to this activity:

Significant weakening of the low-level easterly winds usually initiates an eastward-propagating oceanic Kelvin wave.
Significant equatorial oceanic Kelvin wave activity (dashed and dotted lines) has been present throughout the period shown.

Through January 2024, above-average subsurface temperatures persisted across most of the Pacific Ocean.

From November 2023 through March 2024, below-average temperatures strengthened in the western Pacific Ocean and shifted into the eastern Pacific.

Since late February 2024, another upwelling Kelvin wave has shifted eastward.

Equatorial oceanic Kelvin waves have alternating warm and cold phases. The warm phase is indicated by dashed lines. Down-welling and warming occur in the leading portion of a Kelvin wave, and up-welling and cooling occur in the trailing portion.
At times, the Madden Julian Oscillation (MJO) has contributed to the eastward propagation of low-level wind anomalies. An eastward propagating pattern of westerly and easterly wind anomalies was evident starting in November 2023.
Upper-level (200-hPa) Velocity Potential Anomalies

Since the beginning of the period, regions of anomalous divergence (green shading) and convergence (brown shading) were generally propagating eastward.

From early December 2023 to mid-March 2024, anomalous divergence persisted over the central Pacific.

Unfavorable for precipitation (brown shading)
Favorable for precipitation (green shading)
Note: Eastward propagation is not necessarily indicative of the Madden-Julian Oscillation (MJO).
Outgoing Longwave Radiation (OLR) Anomalies

Through early March 2024, negative OLR anomalies (more convection) persisted over the central equatorial Pacific Ocean.

Through December 2023, positive OLR anomalies persisted around Indonesia.

From mid-December 2023 through March 2024, OLR anomalies shifted eastward from the Indian Ocean/Indonesia to the western Pacific/Date Line.

Since early May 2024, OLR was below-average in the western equatorial Pacific.

Drier-than-average Conditions (orange/red shading)
Wetter-than-average Conditions (blue shading)
The ONI is based on SST departures from average in the Niño 3.4 region, and is a principal measure for monitoring, assessing, and predicting ENSO.

Defined as the three-month running-mean SST departures in the Niño 3.4 region. Departures are based on a set of improved homogeneous historical SST analyses (Extended Reconstructed SST - ERSST.v5). The SST reconstruction methodology is described in Huang et al., 2017, J. Climate, vol. 30, 8179-8205.)

It is one index that helps to place current events into a historical perspective.

Note: a different SST dataset is used for weekly SST monitoring (slides #4-9) and is using OISSTv2.1 (Huang et al., 2021).
El Niño: characterized by a positive ONI greater than or equal to +0.5°C.

La Niña: characterized by a negative ONI less than or equal to -0.5°C.

By historical standards, to be classified as a full-fledged El Niño or La Niña episode, these thresholds must be exceeded for a period of at least 5 consecutive overlapping 3-month seasons.

CPC considers El Niño or La Niña conditions to occur when the monthly Niño3.4 OISST departures meet or exceed +/- 0.5°C along with consistent atmospheric features. These anomalies must also be forecasted to persist for 3 consecutive months.
The most recent ONI value (February - April 2024) is 1.1°C.
Historical El Niño and La Niña Episodes Based on the ONI computed using ERSST.v5

Recent Pacific warm (red) and cold (blue) periods based on a threshold of +/- 0.5 °C for the Oceanic Niño Index (ONI) [3 month running mean of ERSST.v5 SST anomalies in the Nino 3.4 region (5N-5S, 120-170W)]. For historical purposes, periods of below and above normal SSTs are colored in blue and red when the threshold is met for a minimum of 5 consecutive overlapping seasons.

The ONI is one measure of the El Niño-Southern Oscillation, and other indices can confirm whether features consistent with a coupled ocean-atmosphere phenomenon accompanied these periods. The complete table going back to DJF 1950 can be found [here](#).

A transition from El Niño to ENSO-neutral is imminent, with ENSO-neutral favored in April-June and May-July 2024. La Niña may develop in June-August 2024 (49% chance) or July-September (69% chance).
The majority of models indicate a transition to ENSO-neutral during April-June 2024. After a brief period of ENSO-neutral conditions, most models indicate a transition to La Niña around July-September 2024.
The CFS.v2 ensemble mean (black dashed line) indicates El Niño may transition to ENSO-neutral in May, followed by a transition to La Niña around June-August 2024.
Atmospheric anomalies over the North Pacific and North America During the Last 60 Days

From mid-March through early May, below-average heights and temperatures generally persisted in the eastern North Pacific Ocean and/or western contiguous U.S.

For most of the period, above-average heights and temperatures have persisted over the central and eastern U.S.
Atmospheric anomalies over the North Pacific and North America During the Last 60 Days

From mid-March through early May, below-average heights and temperatures generally persisted in the eastern North Pacific Ocean and/or western contiguous U.S.

For most of the period, above-average heights and temperatures have persisted over the central and eastern U.S.
Atmospheric anomalies over the North Pacific and North America During the Last 60 Days

From mid-March through early May, below-average heights and temperatures generally persisted in the eastern North Pacific Ocean and/or western contiguous U.S.

For most of the period, above-average heights and temperatures have persisted over the central and eastern U.S.
U.S. Temperature and Precipitation Departures During the Last 30 Days

End Date: 11 May 2024
U. S. Seasonal Outlooks
May - July 2024

The seasonal outlooks combine the effects of long-term trends, soil moisture, and, when appropriate, ENSO.
ENSO Alert System Status: El Niño Advisory / La Niña Watch

El Niño is transitioning toward ENSO-neutral.*

Equatorial sea surface temperatures (SSTs) are above average in the western and central Pacific Ocean, and below-average SSTs are emerging in parts of the eastern Pacific Ocean.

A transition from El Niño to ENSO-neutral is likely in the next month. La Niña may develop in June-August 2024 (49% chance) or July-September (69% chance).*
