Attribution of Seasonal Climate Anomalies
November-December-January 2016/2017
• Goal

– In the context of seasonal climate variability and its prediction, utilize seasonal climate forecasts and atmospheric general circulation model (AGCM) simulations to attribute causes for the observed seasonal climate anomalies.

– The analysis can also be considered as an analysis of predictability of the observed seasonal climate anomalies.
Outline

• Methodology
• Data description
• Observed seasonal anomalies
• Ensemble average seasonal mean anomalies from AGCM simulations and initialized forecasts
• Seasonal mean anomalies from the individual AGCM simulations and initialized forecasts
• Summary
• References
• Compare observed seasonal mean anomalies with those from model simulations and forecasts.
• Ensemble averaged of model simulated/predicted seasonal mean anomalies are an indication of the predictable (or attributable) component of the corresponding observed anomalies.
• For seasonal mean atmospheric anomalies, predictability could be due to
  – Anomalous boundary forcings [e.g., sea surface temperature (SSTs); soil moisture etc.];
  – Atmospheric initial conditions.
• The influence of anomalous boundary forcings (particularly due to SSTs, can be inferred from the ensemble mean of AGCM simulations forced by observed SSTs, the so called AMIP simulations). This component of predictability (or attributability) is more relevant for longer lead seasonal forecasts.
• The influence of the atmospheric initial state can be inferred from initialized predictions. This component is more relevant for short lead seasonal forecasts.
• The influence of unpredictable component in the atmospheric variability can be assessed from the analysis of individual model simulations, and the extent anomalies in individual runs deviate from the ensemble average anomalies.
• The relative magnitude of ensemble averaged seasonal mean anomalies to the deviations of seasonal mean anomalies in the individual model runs is a measure of seasonal predictability (or the extent observed anomalies are attributable).
• Observed anomalies are equivalent to a realization of a single model run, and therefore, analysis of individual model runs also gives an appreciation of how much observed anomalies can deviate from the component that are attributable (Kumar et al. 2013).
Data

• Observations
  – SST: NCDC daily OI analysis (Reynolds et al., 2007)
  – Prec: CMAP monthly analysis (Xie and Arkin, 1997)
  – T2m: GHCN-CAMS land surface temperature monthly analysis (Fan and van den Dool, 2008)
  – 200mb height (z200): CFSR (Saha et al., 2010)

• 0-month-lead seasonal mean forecasts from CFSv2 (Saha et al. 2014)
  – **0-month-lead**: the seasonal mean forecasts based on 40 members from the latest 10 days before the target season;
  – **0-month-lead-monthly**: the seasonal mean forecasts constructed from 3 individual monthly forecasts with the latest 10 days initial conditions for each individual monthly forecasts. This approach for constructing seasonal mean anomalies has more influence from the initial conditions (Kumar et al. 2013)

• Seasonal mean AMIP simulation from CFSv2 (provided by Dr. Bhaskar Jha)
  – 18 members

• All above seasonal mean anomalies are based on 1999-2010 climatology.

• z200 responses to tropical heating in linear model (provided by Dr. Peitao Peng)

• Seasonal mean anomalies of z200, T2m, and Prec forecasted from the Constructed Analog Model (provided by Dr. Peitao Peng)

• CFS AMIP simulations forced with observed sea surface temperatures (18 members ensemble)

• CFSv2 real time operational forecasts
  – 0-month-lead: the seasonal mean forecasts based on 40 members from the latest 10 days before the target season. For example, 2016AMJ seasonal mean forecasts are 40 members from 22-31 March2016 initial conditions.
  – 0-month-lead-monthly: the seasonal mean forecasts constructed from 3 individual monthly forecasts with the latest 10 days initial conditions for each individual monthly forecasts. This approach for constructing seasonal mean anomalies has more influence from the initial conditions (Kumar et al. 2013). For example, the constructed 2016AMJ seasonal mean forecasts are the average of April2016 forecasts from 22-31 March2016 initial conditions, May2016 forecasts from 21-30 April2016 initial conditions, and June2016 forecasts from 22-31 May2016 initial conditions.

• Numbers at the panels indicate the spatial anomaly correlation (AC).

Model Simulated/Forecast Anomalies: Individual Runs
• In this analysis, anomalies from individual model runs are compared against the observed seasonal mean anomalies. The spatial resemblance between them is quantified based on anomaly correlation (AC).
• The distribution of AC across all model simulations is indicative of probability of observed anomalies to have a predictable (or attributable) component.
• One can also look at best and worst match between model simulated/forecast anomalies to assess the range of possible outcomes.

Summary

- The observed tropical SST NDJ2016/17 anomalies were weak; the wave train pattern of z200 response to the tropical heating in the linear model originated from western Pacific-Maritime Continent to west and east N-Pacific, with very weak signal over N. America.
- The SST anomalies over the tropics were forecasted reasonably well in CFSv2.
- For the ensemble means, both the AMIP runs and initialized forecasts captured the major large scale La Niña pattern of Prec anomalies over tropical Pacific; but they didn’t capture well the T2m anomalies globally and Prec over the NA; the CFSv2 ensemble mean of NA Prec were negatively correlated to observation;
- For the individual members, the NA Prec and T2m correlation skills were also low and variations between members were large;
- The Constructed Analog model didn’t forecast well NA anomalies of z200 and Prec neither;
