Attribution of Seasonal Climate Anomalies July-August-September 2022

(https://www.cpc.ncep.noaa.gov/products/people/mchen/AttributionAnalysis/)

Summary of Observed Conditions and Outlooks

- Equatorial tropical Pacific SST anomalies continued in La Nina conditions; in the equatorial and north Atlantic, North Pacific, and equatorial eastern Indian Ocean, SST anomalies were in above normal conditions (slide 4). The large-scale distribution of SST anomalies was predicted well (slide 10);

- AMIP simulations and initialized CFSv2, and other NMME forecasts, all replicated the large-scale distribution of observed precipitation anomalies in tropical latitudes ([a reflection of La Niña conditions](#)) including above normal anomalies in the equatorial eastern Indian Ocean, Maritime Continent and dry conditions in the equatorial western, central Pacific Ocean (slides 11, 37-39). In AMIP simulations, positive rainfall anomalies in the northeast Indian subcontinent were similar to the observation.

- Both AMIP simulations and the initialized CFSv2 predicted most of observed large scale 200mb height anomalies that also resulted in good predictions in the large-scale distribution of temperature anomalies globally, and good prediction of large warm temperature anomalies over North America (slides 12,13,15,16).

- Both AMIP simulation and the initialized CFSv2 predicted the observed positive precipitation anomalies over the southwest monsoon region of North America, while AMIP missed the positive precipitation anomalies over the southeast US (slide 14).

- Monthly mean forecasts from the shorter leads show improved prediction skill for the NA temperature for September 2022 (Slide 34).

# Model Simulated/Forecast Ensemble Mean Anomalies

Model Simulated/Forecast Ensemble Average Anomalies

- **AMIP simulations** forced with observed sea surface temperatures (100 members ensemble)

- CFSv2 real time operational forecasts

  - <u>Seasonal forecast</u>: the seasonal mean forecasts based on 40 members from the latest 10 days before the target season (0-month-lead). For example, 2016AMJ seasonal mean forecasts are 40 members from 22-31 March2016 initial conditions.

  - <u>Reconstructed forecast</u>: the seasonal mean forecasts constructed from 3 individual monthly forecasts with the latest 10 days initial conditions for each individual monthly forecasts. This approach fr constructing seasonal mean anomalies has more influence from the initial conditions (Kumar et al. 2013). For example, the constructed 2016AMJ seasonal mean forecasts are the average of April2016 forecasts from 22-31 March2016 initial conditions, May2016 forecasts from 21-30 April2016 initial conditions, and June2016 forecasts from 22-31 May2016 initial conditions.

- Numbers at the panels indicate the spatial anomaly correlation (AC).

# Model Simulated/Forecast Anomalies: Individual Runs

- In this analysis, anomalies from individual model runs are compared against the observed seasonal mean anomalies. The spatial resemblance between them is quantified based on anomaly correlation (AC).

- The distribution of AC across all model simulations is indicative of probability of observed anomalies to have a predictable (or attributable) component.

- One can also look at best and worst match between model simulated/forecast anomalies to assess the range of possible seasonal mean outcomes.

- For further details see: Kumar, A., M. Chen, M. Hoerling, and J. Eischeid (2013), Do extreme climate events require extreme forcings? Geophys. Res. Lett., 40, 3440-3445. doi:10.1002/grl.50657.

Background & Methodology

Attribution of Seasonal Climate Anomalies

- Goal

  - In the context of prediction of seasonal climate variability, utilize seasonal climate forecasts and atmospheric general circulation model (AGCM) simulations to attribute possible causes for the observed seasonal climate anomalies.

  - The analysis can also be considered as an analysis of predictability of the observed seasonal climate anomalies.

Methodology - 1

- Compare observed seasonal mean anomalies with those from model simulations and forecasts.
- Ensemble averaged model simulated/predicted seasonal mean anomalies are an indication of the predictable (or attributable) component of the corresponding observed anomalies.
- For seasonal mean atmospheric anomalies, predictability could be due to
  - Anomalous boundary forcings [e.g., sea surface temperature (SSTs); soil moisture etc.];
  - Atmospheric initial conditions.
- The influence of anomalous boundary forcings (particularly due to SSTs, can be inferred from the ensemble mean of AGCM simulations forced by observed SSTs, the so called AMIP simulations). This component of predictability (or attributability) is more relevant for longer lead seasonal forecasts.

- The influence of the atmospheric initial state can be inferred from initialized predictions. This component is more relevant for short lead seasonal forecasts.
- The influence of unpredictable component in the atmospheric variability can be assessed from the analysis of individual model simulations, and the extent anomalies in individual runs deviate from the ensemble mean anomalies.
- The relative amplitude of ensemble averaged seasonal mean anomalies to the deviations of seasonal mean anomalies in the individual model runs from the ensemble average is a measure of seasonal predictability (or the extent observed anomalies are attributable).
- Observed anomalies are equivalent to a realization of a single model run, and therefore, analysis of individual model runs also gives an appreciation of how much observed anomalies can deviate from the component that is attributable (Kumar et al. 2013).

Data

- Observations
  - SST: OI version 2 analysis (Reynolds et al., 2007)
  - Prec: CMAP monthly analysis (Xie and Arkin, 1997)
  - T2m: GHCN-CAMS land surface temperature monthly analysis (Fan and van den Dool, 2008)
  - 200mb height (z200): CFSR (Saha et al., 2010)
- 0-month-lead seasonal mean forecasts from CFSv2 (Saha et al. 2014)
  - <u>Seasonal forecast:</u> the seasonal mean forecasts based on 40 members from the latest 10 days before the target season (0-month-lead);
  - <u>Reconstructed forecast:</u> the seasonal mean forecasts constructed from 3 individual monthly forecasts with the latest 10 days initial conditions for each individual monthly forecasts. This approach for constructing seasonal mean anomalies has more influence from the initial conditions (Kumar et al. 2013);
- Seasonal mean AMIP simulation based on GFS_FV3 (provided by Dr. Tao Zhang/CPC)
  - 100 members
- All above seasonal mean anomalies are based on 1991-2020 climatology.
- z200 responses to tropical heating in linear model (provided by Dr. Peitao Peng/CPC)
- Seasonal mean anomalies of z200, T2m, and Prec forecasted from the Constructed Analog Model (provided by Dr. Peitao Peng/CPC)
